USING THE ADUCM320 USER GUIDE

NUMBER NOTATIONS

Table 1. Number Notations

Notation	Description
Bit N	Bits are numbered in little endian format, that is, the least significant bit of a number is referred to as Bit 0.
V[X:Y]	Bit field representation covering Bit X to Bit Y of a value or a field (V).
0xNN	Hexadecimal (Base 16) numbers are preceded by the prefix 0x.
0bNN	Binary (Base 2) numbers are preceded by the prefix 0b.
NN	Decimal (Base 10) numbers are represented using no additional prefixes or suffixes.

REGISTER ACCESS CONVENTIONS

Table 2. Register Access Conventions

Mode	Description
RW	Memory location has read and write access.
RC	Memory location is cleared after reading it.
R	Memory location is read access only. A read always returns 0, unless otherwise specified.
W	Memory location is write access only.

MMR bits that are not documented are reserved. Reserved bits should not be changed by the user.

ACRONYMS AND ABBREVIATIONS

Table 3. Acronyms and Abbreviations

Acronym/Abbreviation	Description
ADC	Analog-to-digital converter
DMA	Direct memory access
DDM	Digital diagnostic monitoring
GPIO	General-purpose input and output
LSB	Least significant byte/bit
MDC	Management data input/output clock
MDIO	Management data input/output
MMD	MDIO manageable device (slave)
MMR	Memory mapped register
MSB	Most significant byte/bit
NMI	Nonmaskable interrupt
NVIC	Nested vectored interrupt controller
NVR	Nonvolatile registers
Rx	Receive
SAR	Successive approximation register
SOA	Semiconductor optical amplifier
SPI	Serial peripheral interface
STA	Station management entity (host/master)
SWD	Sync word detect/serial wire debug
Tx	Transmit
UART	Universal asynchronous transmitter
VR	Volatile registers
WDT	Watchdog timer
WUT	Wake-up timer

INTRODUCTION TO THE ADuCM320

The ADuCM320 is a fully integrated single-package device that incorporates high performance analog peripherals together with digital peripherals controlled by an 80 MHz ARM Cortex™-M3 processor and integral flash for code and data.

The ADC on the ADuCM320 provides 14-bit, 1 MSPS data acquisition on up to 16 input pins that can be programmed to be single-ended or differential. Additionally, chip temperature and supply voltages can be measured. The ADC input voltage is 0 V to V_{REF} . A sequencer is provided that allows a user selected set of ADC channels to be measured in sequence without software involvement during the sequence. The sequence can optionally auto repeat at a user-selectable rate.

Up to eight voltage DACs are provided with output ranges programmable to one of two voltage ranges. The DAC outputs have an enhanced feature of being able to retain their output voltage during a watchdog or software reset sequence. On the ADuCM320, four current output DAC sources are provided. The output currents are programmable with ranges of 0 mA to 150 mA. A low drift band gap reference and a voltage comparator complete the analog input peripheral set.

The microcontroller core is a low power ARM Cortex-M3 processor, a 32-bit RISC machine that offers up to 100 MIPS peak performance. Also integrated on chip are two 128 kB Flash/EE memory and 32 kB of SRAM. The flash comprises two separate 128 kB blocks supporting execution from one flash block and simultaneous writing/erasing of the other flash block.

The ADuCM320 operates from an on-chip oscillator or a 16 MHz external crystal and a PLL at 80 MHz. This clock can optionally be divided down to reduce current consumption. Additional low power modes can be set via software. In the normal operating mode, the ADuCM320 digital core consumes about 300 μ A/MHz.

The device includes an MDIO interface capable of operating at up to 4 MHz. The capability to simultaneously execute from one flash block and write/erase the other flash block makes the ADuCM320 ideal for 40 G/100 G optical applications. User programming is eased by receiving interrupts after PHYADR, DEVADD, and end of frame and by having PHYADR and DEVADD hardware comparators. In addition, the nonerasable kernel code plus flags in user flash can provide assistance to allow user code to robustly switch between the two blocks of user flash code and data spaces as required for MDIO.

The ADuCM320 also integrates a range of on-chip peripherals that can be configured via software control as required in the application. These peripherals include one UART, two I²Cs, two SPI serial I/O communication controllers, GPIO, 32-element programmable logic array, three general-purpose timers, one wake-up timer, and one system watchdog timer. In addition, 16-bit PWMs with seven output signals are provided.

GPIO pins on the device power up in input mode with internal pull-ups on the pins of Port 0 to Port 3 and internal pull-downs on the pins of Port 4 and Port 5. In output mode, the software can choose between open-drain mode and push-pull mode. The outputs can drive at least 4 mA. The pull-ups can be disabled and enabled in software. In GPIO mode, the inputs can always be enabled to monitor the pins. The GPIO pins can also be programmed to handle digital or analog peripheral signals, in which case the pin characteristics are matched to the specific requirement.

A large support ecosystem is available for the ARM Cortex-M3 processor, which eases product development of the ADuCM320. Access is via the JTAG serial wire interface. On-chip factory firmware supports in-circuit serial download via MDIO. These features are incorporated in a low cost QuickStart development system supporting this precision analog microcontroller family.

MAIN FEATURES OF ADUCM320

ADC

- Multichannel, 14-bit, 1 MSPS SAR ADC
- Low drift on-chip voltage reference

DACs

- Eight voltage output DACs
 - VDACs are 12-bit monotonic
- Four current output DACs
 - Current DACs are 12-bit monotonic
- Low drift, on-chip 2.5 V voltage reference source
 - Two buffered reference outputs

Communication

- UART
 - Industry standard, 16,450 UART peripheral
 - Support for DMA
- Two I²Cs
 - 2-byte transmit and receive FIFOs for the master and slave
 - Support for DMA
- Two SPIs
 - Master or slave mode with separate 4-byte Rx and Tx FIFOs
 - Rx and Tx DMA channels
- 16-bit PWM with seven output channels
- Multiple GPIO pins

Processing

- ARM Cortex-M3 processor, operating from an internal 80 MHz system clock
- Two 128 kB Flash/EE memory, 32 kB SRAM
- In-circuit download and debug via serial wire
- On-chip UART download capability

On-Chip Peripherals

- Three general-purpose timers
- Wake-up timer
- Watchdog timer
- 32-element programmable logic array (PLA)

Packages and Temperature Range

- 6 mm × 6 mm, 96-ball BGA package, –40°C to +85°C

Tools

- Low cost development system
- Third-party compiler and emulator tool support

Applications

- Optical networking—10 G, 40 G, and 100 G modules
- Industrial control and automation systems
- Smart sensors, precision instrumentation
- Base station systems

MEMORY ORGANIZATION

The [ADuCM320](#) memory organization is described in this section.

Features

- Cortex-M3 memory system features
 - Predefined memory map.
 - Support for bit-band operation for atomic operations.
 - Unaligned data access.
- [ADuCM320](#) on-chip peripherals are accessed via memory mapped registers, situated in the bit-band region.
- User memory sizes options:
 - 32 kB SRAM
 - Two 128 kB Flash/EE memory
- On-chip kernel for manufacturer data and in-circuit download

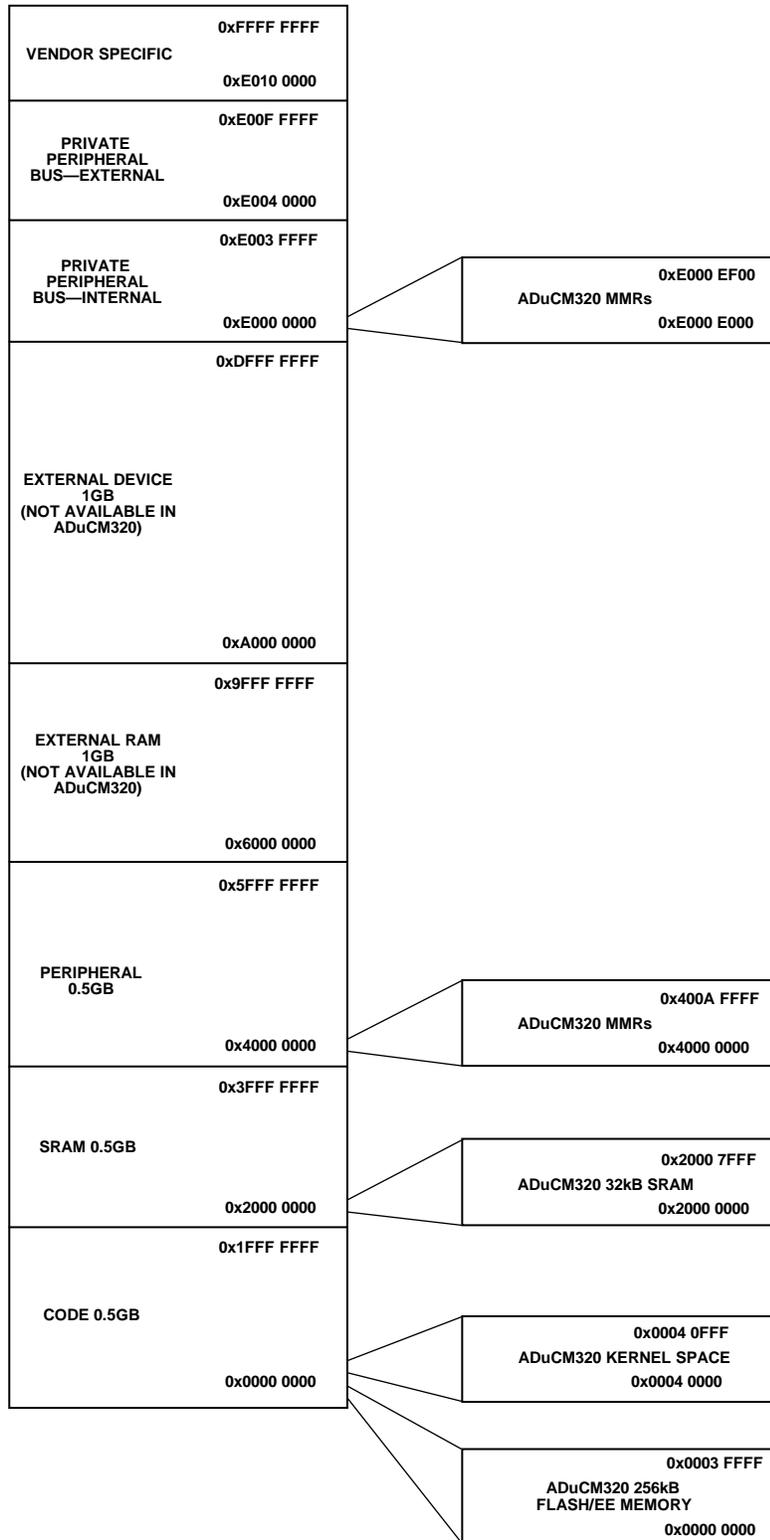

Figure 2. Cortex-M3 Memory Map Diagram

11176-902

CLOCKING ARCHITECTURE

CLOCKING ARCHITECTURE FEATURES

The [ADuCM320](#) integrates two on-chip oscillators and circuitry for an external crystal and external clock source:

- LFOSC is a 32 kHz low power internal oscillator that is used in low power modes.
- HFOSC is a 16 MHz internal oscillator that is used in active mode. This is the default input to the PLL.
- HFXTAL is a 16 MHz external crystal oscillator.
- External clock input (ECLKIN) via GPIO pin.

CLOCKING ARCHITECTURE BLOCK DIAGRAM

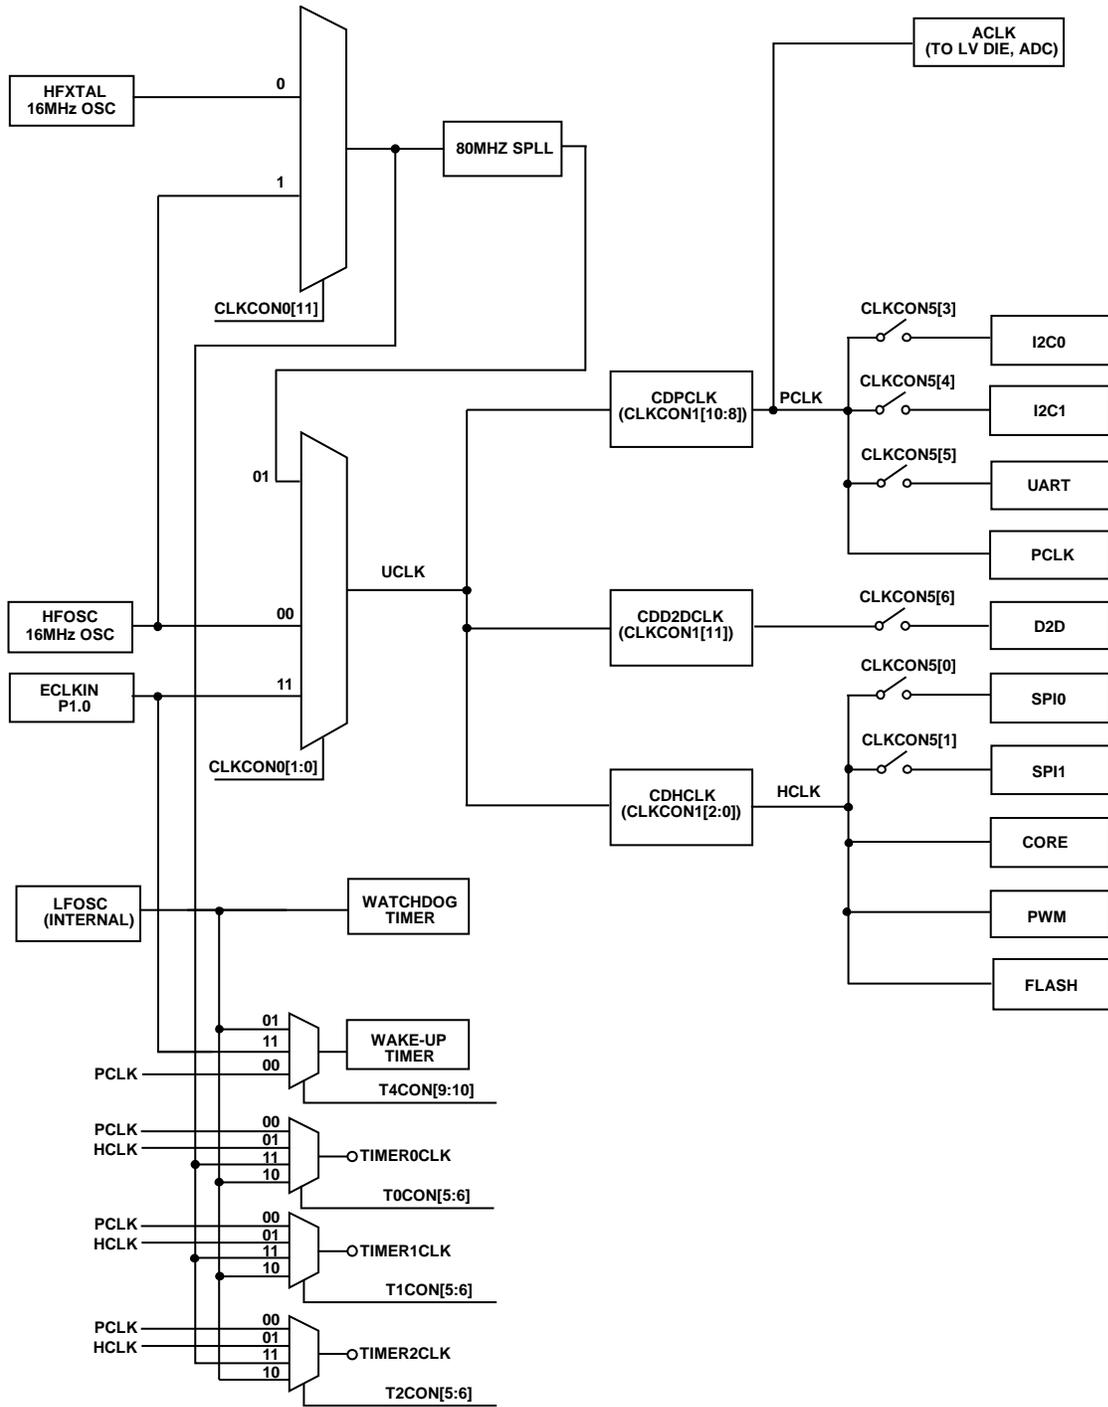

Figure 3. Clocking Architecture Block Diagram

11176-003

CLOCKING ARCHITECTURE OVERVIEW

The system clock, UCLK, can be selected from a 16 MHz oscillator or from an 80 MHz PLL output (default). An external clock on P1.0 can also be used for test purposes.

Internally, the system clock is divided into separate clocks:

- UCLK system clock
- HCLK for the flash, SRAM, and DMA
- PCLK for most peripherals
- ACLK for the analog section of the chip; this is based on PCLK output and goes to the low voltage analog die

All ADC performance details are based on a 20 MHz ACLK (CLKCON1[10:8] = 0b010). Performance at other clock speeds is not guaranteed; therefore, CLKCON1[10:8] should not be changed when the ADC is being used.

CLOCKING ARCHITECTURE OPERATION

At power-up, the processor executes at 80 MHz, sourced from the 80 MHz PLL output. The clock source for the 80 MHz PLL is the internal 16 MHz oscillator by default. User code can select the clock source for the system clock and can divide the clock by a factor of 1 to 128, where the clock divider bits are controlled by CLKCON1[2:0]. This allows slower code execution and reduced power consumption.

Note that P1.0 must be configured as a clock input before the clock source is switched in the clock control register.

User Clock Gating Control Register

Address: 0x40028014, Reset: 0x0000, Name: CLKCON5

Clock Control 5 is used to control the gates of the peripheral UCLKs.

Table 7. Bit Descriptions for CLKCON5

Bits	Bit Name	Description	Reset	Access
[15:7]	RESERVED	Reserved. Always returns 0 when read.	0x0	R
6	D2DCLKOFF	D2D clock user control. This bit disables the UCLK_D2D clock. It controls the gate on the UCLK_D2D in power modes 0, 1 and 2. In power modes 3, this bit has no effect. 0: Clock on 1: Clock off	0x0	RW
5	UCLKUARTOFF	UART clock user control. This bit disables the UCLK_UART clock. It controls the gate on UCLK_UART in power modes 0 and 1. In power modes 2 and 3 the UCLK_UART is always off and this bit has no effect. 0: Clock on 1: Clock off	0x0	RW
4	UCLKI2C1OFF	I2C1 clock user control. This bit disables the UCLK_I2C1 clock. It controls the gate on UCLK_I2C1 in power modes 0 and 1. In power modes 2 and 3, the I2C1 UCLK is always off and this bit has no effect. 0: Clock on 1: Clock off	0x0	RW

Bits	Bit Name	Description	Reset	Access
3	UCLKI2C0OFF	I2C0 clock user control. This bit disables the UCLK_I2C0 clock. It controls the gate on UCLK_I2C0 in power modes 0 and 1. In power modes 2 and 3 the UCLK_I2C0 is always off and this bit has no effect. 0: Clock on 1: Clock off	0x0	RW
2	RESERVED		0x0	R
1	UCLKSPI1OFF	SPI1 clock user control. This bit disables the UCLK_SPI1 clock. It controls the gate on UCLK_SPI1 in power modes 0 and 1. In power modes 2 and 3 the UCLK_SPI1 is always off and this bit has no effect. 0: Clock on 1: Clock off	0x0	RW
0	UCLKSPI0OFF	SPI0 clock user control. This bit disables the UCLK_SPI0 clock. It controls the gate on UCLK_SPI0 in power modes 0 and 1. In power modes 2 and 3, the UCLK_SPI0 is always off and this bit has no effect. 0: Clock on 1: Clock off	0x0	RW

POWER MANAGEMENT UNIT

POWER MANAGEMENT UNIT FEATURES

The power management unit (PMU) controls the different power modes of the ADuCM320.

Four power modes are available:

- Active
- CORE_SLEEP
- SYS_SLEEP
- Hibernate

POWER MANAGEMENT UNIT OVERVIEW

The Cortex-M3 sleep modes are linked to the PMU modes and are described in this section. The PMU is in the always-on section. Each mode gives a power reduction benefit with a corresponding reduction in functionality.

POWER MANAGEMENT UNIT OPERATION

The debug tools can prevent the Cortex-M3 from fully entering its power saving modes by setting bits in the debug logic. Only a power-on reset resets the debug logic. Therefore, the device should be power cycled after using serial wire debug with application code containing the WFI instruction.

Power Mode: Active Mode, Mode 0

The system is fully active. Memories and all user enabled peripherals are clocked, and the Cortex-M3 processor is executing instructions. Note that the Cortex-M3 processor manages its internal clocks and can be in a partial clock gated state. This clock gating affects only the internal Cortex-M3 processing core. Automatic clock gating is used on all blocks and is transparent to the user. User code can use a WFI command to put the Cortex-M3 processor into sleep mode; it is independent of the power mode settings of the PMU.

When the ADuCM320 wakes up from any of the low power modes, the device return to Mode 0.

Power Mode: CORE_SLEEP Mode, Mode 1

In CORE_SLEEP mode, the system gates the clock to the Cortex-M3 core after the Cortex-M3 has entered SLEEP mode. The rest of the system remains active. No instructions can be executed; however, DMA transfers can continue to occur between peripherals and memories. The Cortex-M3 processor FCLK is active, and the device wakes up using the NVIC.

Power Mode: SYS_SLEEP Mode, Mode 2

In SYS_SLEEP mode, the system gates HCLK (system bus clock) and PCLK (peripheral bus clock) after the Cortex-M3 has entered sleep mode. The gating of these clocks stops all AHB attached masters/slaves and all peripherals attached to APB. Peripheral clocks are all off, and they are no longer user programmable. The NVIC (interrupt controller) clock (FCLK) remains active, and the NVIC processes wake-up events.

Power Mode: Hibernate Mode, Mode 3

In hibernate mode, the system disables power to all combinational logic and places sequential logic in retain mode. Because FCLK is stopped, the number of sources capable of waking up the system is restricted. The sources listed in Table 54 are the only sources able to wake up the system.

Power Mode 1 to Power Mode 3 should be entered when the processor is not in an interrupt handler. If Power Mode 1 to Power Mode 3 is entered when the processor is in an interrupt handler, the power-down mode can be exited only by a reset or a higher priority interrupt source.

REGISTER SUMMARY: POWER MANAGEMENT UNIT

Table 8. Power Management Register Summary

Address	Name	Description	Reset	RW

Address: 0x40002400, Reset: 0x0000, Name: PWRMOD

Table 9. Bit Descriptions for PWRMOD

Bits	Bit Name	Description	Reset	Access
[14:2]	RESERVED	Reserved. These bits should be written 0 by user code.	0x0	R
[1:0]	PWRMOD	Power modes control bits. When read, these bits contain the last power mode value entered by user code. Note that in order to place the Cortex in “sleepdeep” mode for hibernate, the Cortex M3 System Control Register (address 0xE000ED10) must be configured to 0x4 or 0x06. 00: Active Mode 01: CORE_SLEEP Mode 10: SYS_SLEEP Mode 11: Hibernate Mode	0x0	RW

Key Protection for PWRMOD Register

Address: 0x40002404, Reset: 0x0000, Name: PWRKEY

Table 10. Bit Descriptions for PWRKEY

Bits	Bit Name	Description	Reset	Access
[15:0]	PWRKEY	Power control key register. The PWRMOD register is key-protected. Two writes to the key are necessary to change the value in the PWRMOD register. First 0x4859, then 0xF27B. The PWRMOD register should then be written. A write to any other register before writing to PWRMOD will return the protection to the lock state.	0x0	RW

ARM CORTEX-M3 PROCESSOR

ARM CORTEX-M3 PROCESSOR FEATURES

High Performance

- 1.25 DMIPS/MHz.
- Many instructions, including multiply, are single cycle.
- Separate data and instruction buses allow simultaneous data and instruction accesses to be performed.
- Optimized for single-cycle flash usage.

Low Power

- Low standby current.
- Core implemented using advanced clock gating so that only the actively used logic consumes dynamic power.
- Power-saving mode support (sleep and deep sleep modes). The design has separate clocks to allow unused parts of the processor to be stopped.

Advanced Interrupt Handling

- The nested vectored interrupt controller (NVIC) supports up to 240 interrupts. The [ADuCM320](#) supports 49 of these interrupts. The vectored interrupt feature greatly reduces interrupt latency because there is no need for software to determine which interrupt handler to serve. In addition, there is no need to have software to set up nested interrupt support.
- The ARM Cortex-M3 processor automatically pushes registers onto the stack at the entry interrupt and retrieves them at the exit interrupt. This reduces interrupt handling latency and allows interrupt handlers to be normal C functions.
- Dynamic priority control for each interrupt.
- Latency reduction using late arrival interrupt acceptance and tail-chain interrupt entry.
- Immediate execution of a nonmaskable interrupt request for safety critical applications.

System Features

- Support for bit-band operation and unaligned data access.
- Advanced fault handling features include various exception types and fault status registers.

Debug Support

- Serial wire debug interfaces (SW-DP).
- Flash patch and breakpoint (FPB) unit for implementing breakpoints. Limited to two hardware breakpoints.
- Data watchpoint and trigger (DWT) unit for implementing watchpoints trigger resources and system profiling. Limited to two hardware watchpoints.

ARM CORTEX-M3 PROCESSOR OVERVIEW

The [ADuCM320](#) contains an embedded ARM Cortex-M3 processor, Revision r2p1. The ARM Cortex-M3 processor provides a high performance, low cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption while delivering outstanding computational performance and exceptional system response to interrupts.

ARM CORTEX-M3 PROCESSOR OPERATION

Several ARM Cortex-M3 processor components are flexible in their implementation. This section details the actual implementation of these components in the [ADuCM320](#).

Serial Wire Debug (SW/JTAG-DP)

The [ADuCM320](#) only supports the serial wire interface via the SWCLK and SWDIO pins. It does not support the 5-wire JTAG interface.

ROM Table

The [ADuCM320](#) implements the default ROM table.

Nested Vectored Interrupt Controller Interrupts (NVIC)

The ARM Cortex-M3 processor includes a nested vectored interrupt controller (NVIC), which offers several features:

- Nested interrupt support
- Vectored interrupt support
- Dynamic priority changes support
- Interrupt masking

In addition, the NVIC has a nonmaskable interrupt (NMI) input.

The NVIC is implemented on the [ADuCM320](#), and more details are available in the System Exceptions and Peripheral Interrupts section.

Wake-Up Interrupt Controller (WIC)

The [ADuCM320](#) has a modified WIC, which provides the lowest possible power-down current. This feature is transparent to the user and more details are available in the Power Management Unit section. It is not recommended to enter a power saving mode while servicing an interrupt. However, if the part does enter a power saving mode while servicing an interrupt, it can be woken up by only a higher priority interrupt source.

μDMA

The [ADuCM320](#) implements the ARM μDMA. More details are available in the DMA Controller section.

ADC CIRCUIT

ADC CIRCUIT FEATURES

- The analog-to-digital converter (ADC) incorporates a fast, multichannel, 16-bit ADC. The ADC is specified to be 14-bit accurate.
- Flexible input multiplexer supporting 16 external inputs and 11 internal channels. The internal channels include the following:
 - Temperature sensor channel.
 - Internal 2.5 V reference.
 - External reference.
 - 4 × IDAC channels. These are the voltage at each of the IDAC output pins.
 - PVDD2 supply voltage.
 - IOVDD/2 supply voltage.
 - AVDD/2 supply voltage.
- Input buffer can be selected for any channel to allow very low input current/input leakage specifications on these input channels.
- High precision, low drift internal 2.5 V reference source.
- An external reference can also be connected to the ADC_REFP and ADC_REFN pins.
- Programmable ADC update rate from 19.55 kSPS to 1 MSPS.
- Internal digital comparator for the AIN4 channel. An interrupt can be generated if the digital comparator detects an ADC result above/below a user defined threshold.
- Each channel has its own distinct data register for its conversion result. For example, when AIN0 is selected, the result appears in ADCDAT0; if AIN7 is selected, the result appears in ADCDAT7. For a differential measurement, the result always appears in the data register of the positive channel.

ADC CIRCUIT BLOCK DIAGRAM

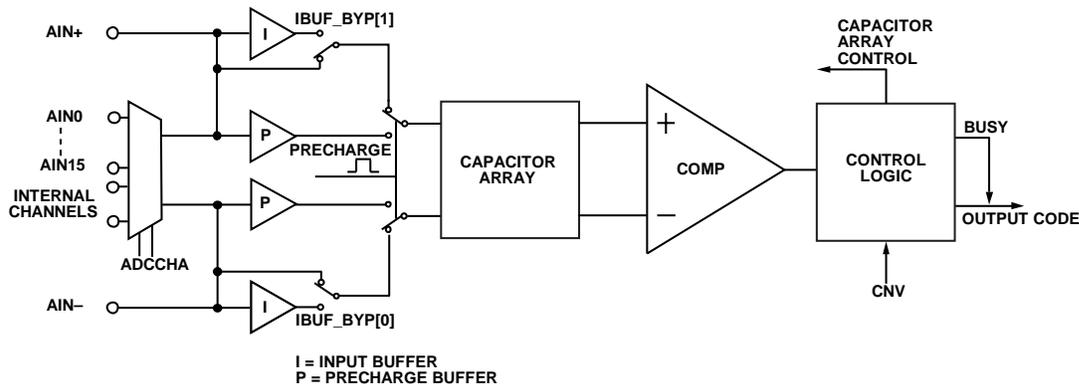

Figure 4. ADC Circuit Block Diagram

11176-004

ADC CIRCUIT OVERVIEW

The analog-to-digital converter (ADC) incorporates a fast, multichannel, 16-bit ADC. The ADC is specified to be 14-bit accurate. It can operate from a 2.9 V to 3.6 V supply and is capable of providing a throughput of up to 1 MSPS. This ADC block provides the user with a multichannel multiplexer, input buffer for high impedance input channels, on-chip reference, and successive approximation register (SAR) ADC.

The SAR ADC circuit is implemented on the low voltage analog die. The ARM Cortex-M3 processor interfaces to the ADC via an internal parallel die-to-die interface.

Depending on the input signal configuration, the ADC can operate in one of the following two modes:

- Differential mode—to measure the difference between two signals.
- Single-ended mode—to measure any signal relative to AGND.

The converter accepts an analog input range of 0 to V_{REF} when operating in single-ended mode. In fully differential mode, the input signal must be balanced around a common-mode voltage (V_{CM}) in the range 0 V to AV_{DD} and with a maximum amplitude of $2 \times V_{REF}$.

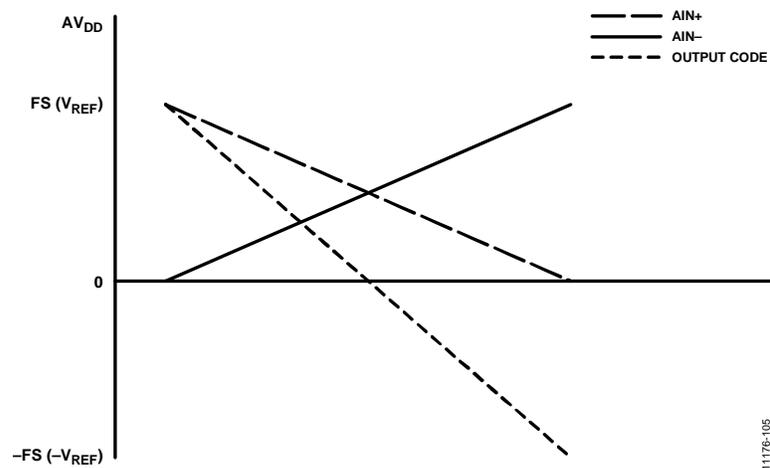

Figure 5. Examples of Balanced Signals for Differential Mode

A high precision, low drift, factory-calibrated 2.5 V reference is provided on chip. An external reference can also be connected to the ADC_REFP and ADC_REFN pins.

Single or continuous conversion modes can be initiated in software. An external pin (alternate function of P2.4), can also be used to generate a repetitive trigger for ADC conversions.

ADC CIRCUIT OPERATION

The SAR ADC is based on a charge redistribution DAC. The capacitive DAC consists of two identical arrays of 18 binary weighted capacitors that are connected to the two inputs of the comparator.

The ADC converts the voltage applied to AIN+ and AIN- in the following three steps:

1. Precharge phase: During this phase, the precharge buffers connect the inputs to the capacitor arrays. This charges the capacitors quickly with minimal loading of the external input source.
2. Acquisition phase: During the acquisition phase, the capacitor arrays are connected directly to the inputs to fully charge the capacitor arrays and eliminate any precharge buffer errors. The timing for the acquisition phase is set by ADCCNVC[25:16]. This value should be set to 500 ns. If the input buffer is not used when measuring $AV_{DD}/2$, $IOV_{DD}/2$, or temperature sensor channels, set this value to 1.5 μ s.
3. Conversion phase: At the end of the acquisition phase, the internal CNV signal goes high and initiates the conversion phase. The conversion begins with the SW+ and SW- switches being opened. This disconnects the two capacitor arrays from the analog inputs and connects the analog inputs to the AGND (V_{REF-}) input. The conversion is completed by normal successive approximation.

The ADC block operates from an internally generated 20 MHz clock.

The ADC conversion rate is set by ADCCNVC[9:0].

ADC TRANSFER FUNCTION

Single-Ended Mode

In single-ended mode, the input range is 0 to V_{REF} . The output coding is straight binary with

$$1 \text{ LSB} = FS/65,536; \text{ or,}$$

$$V_{REF}/65,536 = 2.5 \text{ V}/65,536 = 38.14 \mu\text{V}$$

The data values in ADCDATx are aligned such that the MSB is in ADCDATx[27] and, therefore, the LSB is in ADCDATx[12]. The ideal code transitions occur midway between successive integer LSB values (that is, 1/2 LSB, 3/2 LSB, 5/2 LSB, ..., FS - 3/2 LSB). The ideal input/output transfer characteristic is shown in Figure 6.

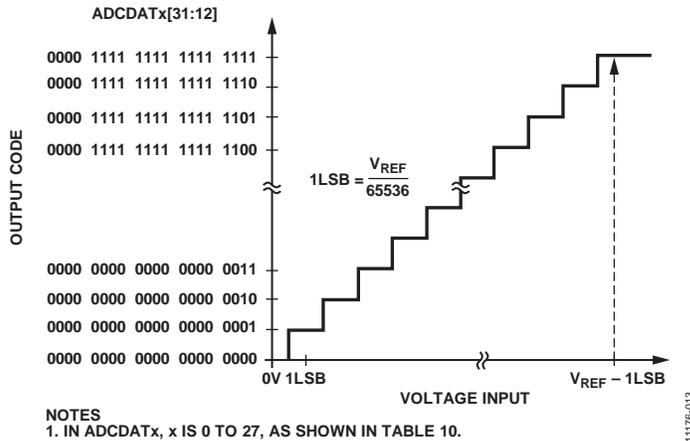

Figure 6. ADC Transfer Function: Single-Ended Mode

Differential Mode

The amplitude of the differential signal is the difference between the signals applied to the AIN+ and AIN- pins (that is, $A_{IN+} - A_{IN-}$). The maximum amplitude of the differential signal is, therefore, $-V_{REF}$ to $+V_{REF}$ p-p ($2 \times V_{REF}$). This is regardless of the common mode (CM). The common mode is the average of the two signals ($A_{IN+} + A_{IN-}$)/2 and is, therefore, the voltage that the two inputs are centered on. This results in the span of each input being $CM \pm V_{REF}/2$. This voltage must be set up externally, and its range varies with V_{REF} . The voltage at the AIN+ and AIN- pins must be within the allowed input voltage range.

The output coding is twos complement in fully differential mode, with

$$1 \text{ LSB} = 2 \times V_{REF}/65,536; \text{ or,}$$

$$2 \times 2.5 \text{ V}/65,536 = 76.29 \mu\text{V}$$

where $V_{REF} = 2.5 \text{ V}$.

The data values in ADCDATx are aligned such that the MSB is in ADCDATx[27] and, therefore, the LSB is in ADCDATx[13]. The ideal input/output transfer characteristic is shown in Figure 7.

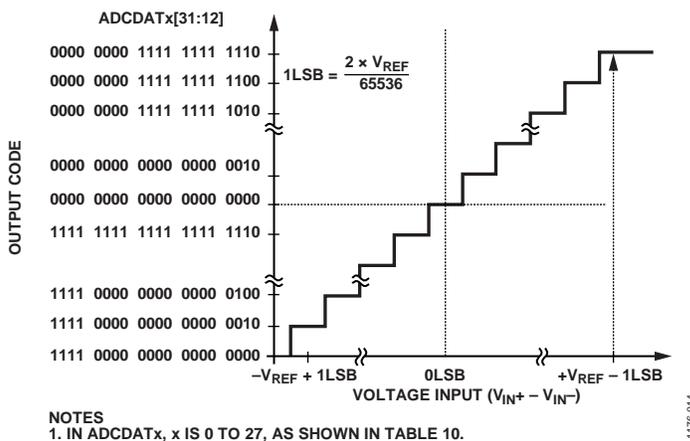

Figure 7. ADC Transfer Function: Differential Mode

ADC TYPICAL SETUP SEQUENCE

After being configured via the ADC control and channel selection registers, the ADC converts the analog input and provides a 16-bit result in the ADC data registers.

The following is an example sequence to set up the ADC and generate a single conversion on AIN0 using a single-ended measurement:

1. Configure the device as follows:

```
ADCCON = 0x280;           // Power up the ADC, enable reference buffer, idle mode.
ADCCHA = 0x1100;         // Select AIN0 as the positive ADC input (AIN+) and ADC_REFN as
the negative ADC input (AIN-).
ADCCNVC = 0xA00C8;      // Select 100 kSPS ADC update rate and 500 ns acquisition time.
ADCCON |= 0x2;          // Enable single conversion.
```

2. Wait for LV die interrupt
3. `iADCRESULT = ADCDAT0;` // Read the ADC result.)

Note that if the ADC is set from continuous conversion mode to idle mode after a full ADC sequence is completed, `ADCSEQ[31]` must be set to 1 before starting another sequence and reconfiguring the ADC back to continuous conversion mode. This ensures that the sequencer restarts with the first selected channel in `ADCSEQ`.

ADC INPUT BUFFER

An optional input buffer can be enabled for any ADC input channel on the [ADuCM320](#).

The control register `IBUFCON` controls the input buffer switches as follows:

- `IBUF_BYP` (`IBUFCON[1:0]`) controls the bypass switches on the ADC input buffer. If the input buffer is required on either the positive or negative input, the bypass switch must be turned off.
- `IBUF_PD` (`IBUFCON[3:2]`) powers up or powers down the ADC input buffer.

ADC INTERNAL CHANNELS

Temperature Sensor Settings

The [ADuCM320](#) provides a voltage output from an on-chip band gap reference that is proportional to the absolute temperature of the low voltage die. This voltage output is routed through the front end of the ADC multiplexer (effectively, an additional ADC channel input), facilitating an internal temperature sensor channel that measures die temperature.

The internal temperature sensor is not designed for use as an absolute ambient temperature calculator. Its intended use is as an approximate indicator of the temperature of the [ADuCM320](#) low voltage analog die.

An ADC temperature sensor conversion differs from a standard ADC voltage. The ADC performance specifications do not apply to the temperature sensor.

When the temperature sensor channel is selected, the ADC update rate should be 80 kSPS.

The ADC automatically changes the ADC update rate to 80 kSPS when the temperature sensor, `AVDD/2`, or `IOVDD/2` input channel is selected. If a different ADC sampling rate is required for other channels after the conversion on any of these three channels is completed, the `ADCCNVC` register must be updated.

Note that when the sequencer is enabled and includes any of these three channels, the value in the `ADCCNVC` register does not change and the ADC sampling rate does not change.

The temperature sensor settings are as follows:

Enable the temperature sensor on the ADC; set `ADCCHA[12:0] = 0x1116`.

To calculate the die temperature, use the following formula:

$$T - T_{REF} = (V_{ADC} - V_{TREF}) \times K$$

where:

T is the temperature result.

T_{REF} is 25°C.

V_{ADC} is the average ADC result from two consecutive conversions.

V_{TREF} is the ADC result in millivolts that corresponds to $T_{REF} = 25^\circ\text{C}$. The user should measure this in their own application because this value will vary from part to part. The typical value used for demonstration purposes is 1290 mV.

K is the gain of the ADC in temperature sensor mode. The user should determine the gain by performing a two-point temperature calibration because this value will vary from part to part. The typical value used for demonstration purposes only is 4.394 mV/°C.

This corresponds to 1/V TC.

Using the default values from the [ADuCM320](#) data sheet without any calibration, the equation becomes

$$T - 25^\circ\text{C} = (V_{ADC} - 1290) \times 1/K.$$

Therefore, assuming V_{ADC} at 25°C = 1290 mV and slope mV/C = 4.394 mV/C,

$$T = ((V_{ADC} - 1290)/4.394) + 25$$

where:

V_{ADC} is in millivolts.

Check the latest version of the [ADuCM320](#) data sheet for the most up to date figures.

For increased accuracy, perform a two-point calibration at a controlled temperature value.

The values used in this example for V_{TREF} and K are not guaranteed values. The values V_{TREF} and K will vary from part to part; therefore, the user should derive the appropriate values by performing a calibration at ambient temperature.

AVDD/2 and IOVDD/2 Supply Voltage Channels

These supply voltage channels are measured via internal resistor dividers. Because the resistors used are high impedance and the divided voltage is not buffered, a slower ADC update rate should be used.

The ADC automatically changes the ADC update rate to 80 kSPS when the temperature sensor, AVDD/2, or IOVDD/2 input channel is selected. If a different ADC sampling rate is required for other channels after the conversion on any of these three channels is completed, the ADCCNVC register must be updated.

Note that when the sequencer is enabled and includes any of these three channels, the value in the ADCCNVC register does not change and the ADC sampling rate does not change. At rates above 80 kSPS, the accuracy will be reduced if the input buffer is disabled.

ADC SUPPORT CIRCUITS

IDAC Channels

The [ADuCM320](#) allows the voltage on the IDAC output pins to be selected as inputs to the ADC. These channels are useful for determining the power consumed by each IDAC.

ADC Digital Comparator

A digital comparator is provided to allow an interrupt to be triggered if the ADC data result is above or below a programmable threshold. Only the AIN4 external input channel can be used with the digital comparator.

To set up the ADC digital comparator, note the following:

- ADCCMP[17:2] are used to set a 16-bit ADC threshold value.
- ADCCMP[1] configures the comparator to be triggered when the ADC result is above or below the threshold value.
- To enable the ADC comparator interrupt, set INTSEL[2] = 1 to enable the digital comparator to the Low Voltage Die Interrupt 1 signal.
- Similarly, set INTSEL[10] = 1 to enable the digital comparator interrupt to the Low Voltage Die Interrupt 0 signal.
- The comparator output is asserted when the value in ADCDAT4[27:12] rises above the value in ADCCMP[17:2] if ADCCMP[1] = 1. If ADCDAT4[27:12] remains above ADCCMP[17:2], no further comparator interrupts occur. The interrupt only occurs when the comparator circuit detects a rise above the threshold.
- Similarly, if ADCCMP[1] = 0, the comparator output is asserted when the value in ADCDAT4[27:12] falls below the value in ADCCMP[17:2]. If ADCDAT4[27:12] remains below ADCCMP[17:2], no further comparator interrupts occur. The interrupt only occurs when the comparator circuit detects a fall below the threshold value.

ADC Channel Sequencer

An ADC sequencer is provided to reduce the processor overhead of sampling and reading individual channels. The ADC sequencer allows a user to select the number and order of ADC input channels that the ADC will sample and provides a single interrupt source that is asserted when the sequence ends. The sequencer can also be programmed to restart automatically without a delay or with a programmable delay between the end and start of sequences.

Some additional details about the sequencer include the following:

- The sequencer reads the ADCSEQ[0:27] register to determine which channels need to be included and which need to be excluded from the execution sequence.
- ADCSEQ corresponds to the ADCCHA[4:0] for the list of ADC input channels. For example, to include AIN9, set ADCSEQ[9].
- To enable the sequencer as the Low Voltage Die Interrupt 1 source, set INTSEL[1] = 1. To enable the sequencer as the Low Voltage Die Interrupt 0 source, set INTSEL[9] = 1.
- To start the sequencer, set ADCSEQ[31:30] = 0x3.
- The ADCSEQC[27:20] register bits are used to set the delay between finishing one sequence of channels and starting another sequence.
- Normally, single-ended measurements are assumed by the ADC with AGND as the negative reference. However, for Channel 0, Channel 2, Channel 4, and Channel 6, a differential measurement can be selected by configuring the appropriate bits in ADCSEQC[19:0]. For example, ADCSEQC[4:0] selects the negative input when AIN0 is the positive. For single-ended measurements using the sequencer and AIN0, ADCSEQC[4:0] should be set to 0x11 for VREFN_NADC (ADC_REFN pin).
- Care should be taken when using the sequencer if the input buffer is enabled. The IBUFCON register controls the input buffer. If the input buffer is enabled, all channels sampled in a sequence will be sampled with the input buffer enabled. It is recommended to split sequences into the following:
 - Sample unbuffered channels together in one sequence.
 - Sample buffered channels in a separate sequence.
 - If full accuracy results are required for the AVDD/2, IOVDD/2, or temperature channels, then care must be taken when measured with the sequencer.
 - With the input buffer disabled, the acquisition time should be set to 1.5us via ADCCONV[25:16] = 0x1E.
 - Or, alternatively, enable the input buffer.

ADC DMA (Direct Memory Access)

The ADC or the ADC sequencer can be selected as the source channel for the DMA controller. This reduces processor overhead by moving ADC results directly into SRAM with a single interrupt asserted when the required number of ADC conversions has been completely logged to memory.

When using the ADC sequencer with the DMA controller, it is recommended to use DMA autorequest transfer types rather than basic transfer types.

ADC Voltage Reference Selection

The ADuCM320 integrates a low drift, 2.5 V ADC reference source. By default, this internal reference is enabled and selected as the reference source for the ADC. When using the internal 2.5 V voltage reference, ensure the following:

- ADCCON[7] = 1 to power up the internal reference buffer
- AFEREF3[3] = 0 to select the internal reference as the ADC reference source

It is also possible to select an external reference source through the ADC_REFP pin.

To select an external voltage source as the ADC reference source, ensure the following:

- ADCCON[7] = 0 to power down the internal reference buffer
- AFEREF3[3] = 1 to select the external reference as the ADC reference source

The external reference source must be capable of driving the 4.7 μ F capacitor on the ADC_REFP pin.

If switching from the external to internal reference voltage source, note that there is a power-on time specification given in the ADuCM320 data sheet for the ADC reference buffer to fully power up after ADCCON[7] is set to 1.

REGISTER SUMMARY: ADC CIRCUIT

The CPU accesses the ADC circuit over a die to die interface (D2D) which increases the execution times of ldr and str instructions. 32 bit MMRs have addresses 0x40086xxx and take 8 CPU cycles at 80 MHz to execute. 16 bit MMRs have addresses 0x40082xxx and take 6 CPU cycles at 80 MHz to execute.

ADCx Data and Flags Register

Address: 0x40086000 - 0x4008606C (Increments of 0x4), Reset: 0x00000000, Name: ADCDAT0 to ADCDAT27

At the end of each conversion the ADC writes the data to the appropriate ADCDATx MMR, where x is 0 to 27. This process takes 2 ADC clock cycles which at 20MHz means 100ns. During this time the value in ADCDATx can not be read reliably by the CPU. For this reason during this time ADCDATx is forced to zero and specifically bit ADCDATx[3] is zero. Therefore if ADCDATx is read at random times, ADCDATx[3] should be checked and if it is zero ADCDATx should be read again. This second read must be at least 100ns later. This is basically guaranteed by the time used to check the bit plus the time required to read the value via the D2D interface. The user must make sure that the second read does not coincide with any further conversion on that channel. Alternately the user can do repeated reads until the read is successful. At 1MSPs conversion speed the read will be valid 90% of the time while at 100 kSPS it will be valid 99% of the time. When using interrupts, this problem will not occur unless the read happens exactly when a subsequent ADC conversion completes on that channel. This behaviour is valid for all conversion modes (single conversions, repeated conversions and sequencer conversions).

Table 13. Bit Descriptions for ADCDAT0 to ADCDAT27

Bits	Bit Name	Description	Reset	Access
[31:4]	DAT	ADCx data. The numeric value of the conversion is stored in bits 12 to 27. Bits 28 to 31 are the extended sign bits. Bits 3 4 to 11 are always zero. The format is 2's complement (signed int).	0x0	RW

[17:2]	THR	Digital compare threshold. Value to compare to channel 4 data.	0x0000	RW
1	DIR	Select digital comparator direction. 0: ADCTH less than channel 4 data 1: ADCTH larger than channel 4 data	0x0	RW
0	EN	Digital comparator enable. 0: Disable 1: Enable	0x0	RW

ADC Conversion Configuration Register

Address: 0x4008609C, **Reset:** 0x000A00C8, **Name:** ADCCNVC

Note: When ADCCP is set to 22 (Temp Sensor) or 25 (IOVDD/2) or 26 (AVDD/2), the ADCCNVC register automatically changes to 0x7D00FA – (80 kSPS) for single conversions. ADCCNVC should be set to the required conversion rate after sampling these 3x channels if a different sample rate is required for other ADC input channels.

Note, when the sequencer is enabled and includes any of these 3x channels, the value in ADCCNVC does not change and the ADC sampling rate does not change.

Table 18. Bit Descriptions for ADCCNVC

Bits	Bit Name	Description	Reset	Access
[31:26]	Reserved	Do not overwrite		RW
[25:16]	CNVD	Configure ADC Acquisition time and sampling time Acquisition time = CNVD/20 MHz Default acquisition time is 500 ns For best SNR results, ensure the acquisition time is set to >=500 ns for all ADC conversion rates	0xA	RW
[15:10]	Reserved	Do not overwrite		RW
[9:0]	CNVC	Configure Conversion frequency. Conversion Frequency = 20 MHz/CNVC	0xC8	RW

REGISTER SUMMARY: ADDITIONAL REGISTERS

The CPU accesses these additional registers over a die to die interface (D2D) which increases the execution times of ldr and str instructions. 32 bit MMRs have addresses 0x40087xxx and take 8 CPU cycles at 80 MHz to execute. 8 bit MMRs have addresses 0x40081xxx and take 5 CPU cycles at 80 MHz to execute.

ANALOG COMPARATOR

ANALOG COMPARATOR FEATURES

The analog comparator compares two analog signals and gives an output indicating which of the input signals is bigger. This output can generate an interrupt

ANALOG COMPARATOR OVERVIEW

The positive input of the comparator is shared with AIN6.

The negative input of the comparator can be set by software to AVDD/2, AIN5, or DAC7.

The comparator output is connected to the interrupt logic and can be used as described in the System Exceptions and Peripheral Interrupts section.

ANALOG COMPARATOR OPERATION

If required, change the hysteresis with AFECOMP[0], the comparator speed with AFECOMP[1:2], and the output polarity with AFECOMP[3].

Select the input source with AFECOMP[6:7].

Power up and enable the comparator with AFECOMP[8] and AFECOMP[4:5].

REGISTER SUMMARY: ANALOG COMPARATOR

The CPU accesses the ADC circuit over a die to die interface (D2D) which increases the execution times of ldr and str instructions. Accessing AFECOMP takes 8 CPU cycles at 80 MHz to execute.

IDAC Data Register

The IDAC output is controlled by an internal 11-bit and 5-bit DAC.

The 11-bit DAC (IDACxDAT[27:17]) controls the most significant bits. The 5-bit DAC (IDACxDAT[16:12]) controls the LSBs. The two MSBs of the 5-bit DAC (IDACxDAT[16:15]) overlap the two LSBs of the 11-bit DAC (IDACxDAT[18:17]) as shown in Figure 9.

14-BIT IDAC OUTPUT		13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-BIT DAC	IDACxDAT	27	26	25	24	23	22	21	20	19	18	17			
5-BIT DAC											16	15	14	13	12

11176-009

Figure 9. 14-Bit IDAC Output

The 11-bit DAC and the 5-bit DAC are guaranteed monotonic as individual DACs. This combination makes it possible to reach 14-bit resolution—up to 16,384 unique output values. However, monotonicity is only guaranteed for 11 bits ($DNL < -1$ LSB).

IDACs—Common Use Cases**Case 1—Setting the Output Current of IDAC1 to Quarter Scale**

- Set up IDAC1CON to 10xxxx00b:
 - IDAC1CON[7] = 1: enable writes to the IDAC1DAT register
 - IDAC1CON[0] = 0: power up IDAC1
 - IDAC1CON[5:2] as per Table 25: set up the filter bandwidth as required
 - IDAC1CON[1] = 0: disable the IDAC1 pull-down current source
 - IDAC1DAT[3] = 0: clear the IDAC1 sync bit to allow immediate updating of the IDAC
 - IDAC1CON[6] = 0: disable the overtemperature shutdown feature
- Set up IDAC1DAT to give a current output of quarter scale:
 - If IDAC1 is used in an open loop system or in a set and forget type operation, set IDAC1DAT = 0x03FE0000
 - Set IDAC1DAT[27:17] = 0x1FF
- Set IDAC1DAT[16:12] = 0x00
 - If IDAC1 is used in a closed loop system, set IDAC1DAT = 0x03FCF000
 - Set IDAC1DAT[27:17] = 0x1FE
 - Set IDAC1DAT[16:12] = [01111]b
 - Adjust the 5-bit IDAC (IDAC1DAT[16:12]) up or down accordingly to attain the correct setting.

Case 2—Turn On IDAC2 but to Set the Output to 0 mA with the Lowest Possible Offset

Before powering up the IDACs, ensure that the internal reference is fully powered on.

- Set up the IDAC2CON register to 10xxxx00b:
 - IDAC2CON[7] = 1: enable writes to the IDAC2DAT register
 - IDAC2CON[0] = 0: power up IDAC2
 - IDAC2CON[5:2] as per Table 25: set up the filter bandwidth as required
 - IDAC2CON[1] = 0: enable the IDAC2 pull-down current sink
 - IDAC2CON[6] = 0: disable the overtemperature shutdown feature
- Set up the IDAC2DAT register
 - IDAC2DAT[27:12] = 0x0000: set the IDAC to zero scale

REGISTER SUMMARY: IDAC

The CPU accesses the IDAC circuit over a die to die interface (D2D) which increases the execution times of ldr and str instructions. 32 bit MMRs have addresses 0x40086xxx and take 8 CPU cycles at 80 MHz to execute.

VDACS

VDAC FEATURES

The ADuCM320 has eight VDACS. The specified load resistance is greater than 5 k Ω , and the specified capacitance is less than 100 pF.

VDAC BLOCK DIAGRAM

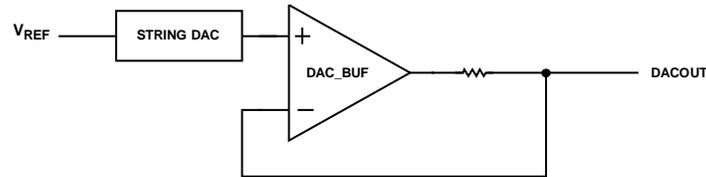

Figure 10. Output Mode Capacitor Load ≤ 100 pF

VDAC OVERVIEW

The ADuCM320 has eight VDACS specified to drive 5 k Ω load, 500 μ A maximum.

The VDACS can select from two reference sources:

- 0 V to internal reference, V_{REF} (0 V to 2.5 V)
- 0 V to AV_{DD} (3.3 V)

VDAC OPERATION

The DAC is configurable through a control register and a data register. The on-chip DAC architecture consists of a resistor string DAC followed by an output buffer amplifier, as shown in Figure 10.

The linearity specification of the DAC when driving a 5 k Ω resistive load to ground is guaranteed through the full transfer function except for Code 0 to Code 100; in 0-to- AV_{DD} mode, the linearity specification is also not guaranteed for Code 3995 to Code 4095. Linearity degradation near ground and AV_{DD} is caused by saturation of the output amplifier; a general representation of its effects (neglecting offset and gain error) is shown in Figure 11.

The dotted line in Figure 11 indicates the ideal transfer function. The solid line represents what the transfer function may look like with endpoint nonlinearities due to saturation of the output amplifier. Figure 11 represents a transfer function in 0-to- AV_{DD} mode only. In 0-to- V_{REF} mode, the lower nonlinearity is similar. However, the upper portion of the transfer function follows the ideal line all the way to the end, showing no signs of endpoint linearity errors.

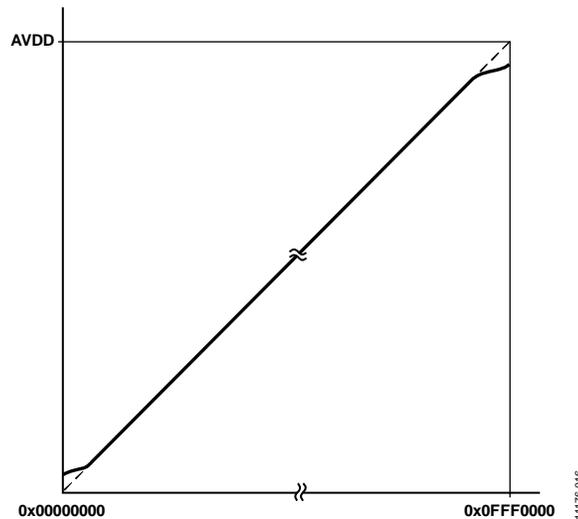

Figure 11. DAC Endpoint Nonlinearities Due to Amplifier Saturation

REGISTER SUMMARY: VDAC

The CPU accesses the VDAC circuit over a die to die interface (D2D) which increases the execution times of ldr and str instructions. 32 bit MMRs have addresses 0x40086xxx and take 8 CPU cycles at 80 MHz to execute. 16 bit MMRs have addresses 0x40082xxx and take 6 CPU cycles at 80 MHz to execute.

SYSTEM EXCEPTIONS AND PERIPHERAL INTERRUPTS

CORTEX-M3 AND FAULT MANAGEMENT

The ADuCM320 integrates an ARM Cortex-M3 processor, which supports several of system exceptions and interrupts generated by peripherals. Table 52 lists the ARM Cortex-M3 processor system exceptions.

Table 52. System Exceptions

Number	Type	Priority	Description
1	Reset	–3 (highest)	Any reset.
2	NMI	–2	Nonmaskable interrupt not connected on the ADuCM320.
3	Hard fault	–1	All fault conditions if the corresponding fault handler is not enabled.
4	Memory management fault	Programmable	Memory management fault; access to invalid locations.
5	Bus fault	Programmable	Prefetch fault, memory access fault, data abort, and other address/memory related faults.
6	Usage fault	Programmable	Same as undefined instruction executed or invalid state transition attempt.
7 to 10	Reserved	N/A	
11	SVCALL	Programmable	System service call with SVC instruction. Used for system function calls.
12	Debug monitor	Programmable	Debug monitor (breakpoint, watchpoint, or external debug requests).
13	Reserved	N/A	
14	PendSV	Programmable	Pendable request for system service. Used for queuing system calls until other tasks and interrupts are serviced.
15	SYSTICK	Programmable	System tick timer.

The peripheral interrupts are controlled by the NVIC and are listed in Table 53. All interrupt sources can wake up the part from Mode 1. Only a limited number of interrupts can wake up the processor from the low power modes (Mode 2 and Mode 3) as shown in Table 53. When the device is woken up from Mode 2 or Mode 3, it returns to Mode 0. If the processor enters any power mode from Mode 1 to Mode 3 while the processor is in an interrupt handler, only an interrupt source with a higher priority than the current interrupt can wake up the part (higher value in IPRx registers).

Two steps are usually required to configure an interrupt

- Configuring a peripheral to generate an interrupt request to the NVIC.
- Configuring the NVIC for that peripheral request.

Table 53. Interrupt Vector Table

Position Number	Vector	Wake-Up Processor from Mode 1	Wake-Up Processor from Mode 2 or Mode 3
0	Wake-up timer	Yes	Yes
1	External Interrupt 0	Yes	Yes

37	DMA Channel 11 (I2C1 master) done	Yes	No
38	DMA Channel 12 (ADC) done	Yes	No
39	DMA Channel 13 (flash) done	Yes	No
40	Reserved		
41	Reserved		
42	Reserved		
43	Reserved		
44	I2C1 slave	Yes	No
45	I2C1 master	Yes	No
46	PLA 2	Yes	No
47	PLA 3	Yes	No
48	GP Timer 2	Yes	No
49	LV Die Interrupt 1	Yes	No
50	PWM trip	Yes	No
51	PWM PAIR0	Yes	No
52	PWM PAIR1	Yes	No
53	PWM PAIR2	Yes	No
54	PWM PAIR3	Yes	No

Internal to the ARM Cortex-M3 processor, the highest user-programmable priority (0) is treated as fourth priority—after a reset, an NMI, and a hard fault. The ADuCM320 implements three priority bits, which means that eight priority levels are available as programmable priorities. Note that 0 is the default priority for all the programmable priorities. If the same priority level is assigned to two or more interrupts, their hardware priority (the lower the position number) determines the order in which the processor activates them. For example, if both SPI0 and SPI1 are Priority Level 1, then SPI0 has higher priority.

To enable an interrupt for any peripheral listed from 0 to 31 in Table 53, set the appropriate bit in the ISER0 register. ISER0 is a 32-bit register, and each bit corresponds to the first 32 entries in Table 53.

For example, to enable External Interrupt 4 interrupt source in the NVIC, set $ISER0[5] = 1$. Similarly, to disable External Interrupt 4, set $ICER0[5] = 1$.

To enable an interrupt for any peripheral listed from 32 to 54 in Table 53, set the appropriate bit in the ISER1 register. ISER1 is a 32-bit register, and ISER1 Bit 0 to Bit 22 correspond to the entries 32 to 54 in Table 53.

For example, to enable the PWM PAIR0 interrupt source in the NVIC, set $ISER1[20] = 1$. Similarly, to disable the PWM PAIR0 interrupt, set $ICER1[20] = 1$.

Alternatively, CMSIS provides a number of useful NVIC functions in the `core_cm3.h` file. The function `NVIC_EnableIRQ(PWM_PAIR0_IRQn)` enables the PWM PAIR0 interrupt. The interrupt can be disabled by calling the `NVIC_DisableIRQ(PWM_PAIR0_IRQn)` function.

To set the priority of a peripheral interrupt, the IPRx bits can be set appropriately or, alternatively, the `NVIC_SetPriority()` function can be called. For example, `NVIC_SetPriority(TIMER0_IRQn, 2)` configures the GP Timer 0 interrupt with a priority level of 2.

Table 54 lists the registers to enable and disable relevant interrupts and set the priority levels. The registers in Table 54 are defined in the CMSIS `core_cm3.h` file which is shipped with tools from third party vendors.

Table 54. NVIC Registers

Address	Analog Devices Header File Name	Description	Access
0xE000E004	ICTR	Shows the number of interrupt lines that the NVIC supports.	R

0xE000ED38	BFAR	Bus fault address.	RW
0xE000EF00	STIR	Software trigger interrupt register.	W

EXTERNAL INTERRUPT CONFIGURATION

Seven external interrupts are implemented. These seven external interrupts can be separately configured to detect any combination of the following type of events:

- Edge: rising edge, falling edge, or both rising and falling edges. An interrupt signal (pulse) is sent to the NVIC upon detecting a transition from low to high, high to low, or on either high to low or low to high.
- Level: high or low. An interrupt signal is generated and remains asserted in the NVIC until the conditions generating the interrupt deassert. The level needs to be maintained for a minimum of one core clock cycle to be detected.

The external interrupt detection unit block is in the always-on section and allows external interrupt to wake up the device when in hibernate mode.

Ensure that the associated GPxIE register bit is enabled for the required external interrupt input. The GPxIE register enables the input path circuit for the external interrupt.

For example, for External Interrupt 0, the following code disables the P0.3 output and enables the input path. The appended code also enables the External Interrupt 0 NVIC interrupt source:

```
pADI_GP0->GPOE &= 0xf7;           //Disable P0.3 output.
pADI_GP0->GPIOE |= 0x8;           //Enable input path for P0.3 input.
pADI_INTERRUPT->EI0CFG |= 0x8;    //External IRQ0 enabled.
NVIC_EnableIRQ(EINT0_IRQn);       //Enable External Interrupt 0 source.
```

LOW VOLTAGE ANALOG DIE INTERRUPT CONFIGURATION

Two interrupt lines are available between the low voltage analog die and the interrupt controller on the digital die.

These two interrupt lines are the outputs of two multiplexers of multiple interrupt sources from the low voltage analog die.

The full list of interrupt sources from the low voltage analog die are as follows:

- ADC software conversion complete interrupt. This is asserted at the end of an ADC conversion when this interrupt source is enabled.
- ADC sequencer complete interrupt. This is the interrupt asserted by the ADC sequencer.
- Analog comparator interrupt. If the input signal is outside the selected threshold, this interrupt is asserted.
- Digital comparator interrupt. If the ADC result is outside the selected threshold, this interrupt is asserted.
- IDAC thermal shutdown interrupt.
- IDAC external reference resistor status interrupt.
- Read ECC interrupt source. Error correction and checking is available on the interface between the digital and analog die. If a read error occurs (for example, an error on the ADC result), this interrupt is asserted.
- Write ECC interrupt source. If the ECC returns an error on a value written to the LV die, this interrupt is asserted.

Low Voltage Die Interrupt 1 is more flexible than Low Voltage Die Interrupt 0. The key differences are as follows:

- Low Voltage Die Interrupt 1 allows all seven different interrupt sources as configured by INTSEL[7:0] to be enabled. In the interrupt handler, the LV1 interrupt source can be determined by the INTSTA register
- Low Voltage Die Interrupt 0 allows only one of the possible seven interrupt sources selected by INTSEL[15:8] to be enabled at a given time. The INTSTA register is not valid for LV Interrupt 0.

To clear an interrupt, set the appropriate bit in the INTCLR register.

Note that there is a delay period required after writing to INTCLR before the associated status bit in the INTSTA register is updated.

If polling is used of the INTSTA register, the following example code can be used:

```
pADI_LV_INT->INTCLR = 0x1; // Clear Irq source
delay(10);
ucLVIrqStatus = pADI_LV_INT->INTSTA;
```

```
// Simple delay routine
void delay (long int length)
{
    while (length >0)
        length--;
}
```

REGISTER SUMMARY: LOW VOLTAGE DIE INTERRUPTS

Table 60. Low Voltage Die Interrupts Register Summary

Address	Name	Description	Reset	RW
0x40083004	INTCLR	Interrupt clear register	0x0000	W

1	ADC_SEQ	ADC sequence interrupt status.	0x0	R
0	ADC_SOFTCONV	ADC software conversion interrupt status.	0x0	R

RESET

RESET FEATURES

There are four kinds of resets:

- External reset
- Power-on reset
- Watchdog timeout
- Software system reset

RESET OPERATION

The software system reset is provided as part of the Cortex-M3 processor. To generate a software system reset, the `NVIC_SystemReset()` function must be called. This effectively writes 0x05FA to the top 16 bits of an AIRCR NVIC register. This function along with other useful functions are defined in the CMSIS header files that are shipped with the tools from third party vendors. The `NVIC_SystemReset()` function is defined in the `core_cm3.h` file.

Analog peripherals have the option of maintaining their state after a software or watchdog reset. This function is enabled by default. It can be disabled using the LVRST register. Note that while debugging, the software tools generally only issue a software reset; therefore, an external reset is needed to return registers to their default values.

The GPIO pins and PLA also have the option of maintaining their state after a software or watchdog reset. By default, this function is enabled. Writing a value of 0x1 to RSTCFG configures the GPIO pins and PLA to reset after a software or watchdog reset. Before writing to this register, 0x2009 must be written to RSTKEY followed by 0x0426. After the two keys are written to RSTKEY, RSTCFG must be immediately written.

The RSTSTA register stores the cause for the reset until it is cleared by writing the RSTSTA register. RSTSTA can be used during a reset exception service routine to identify the source of the reset.

The watchdog timer is enabled by default after a reset. The default timeout period is approximately 32 seconds.

User code should disable the watchdog timer at the start of user code when debugging or if the watchdog timer is not required.

```
pADI_WDT->T3CON = 0x00; // Disable watchdog timer
```

Table 64. Device Reset Implications

Reset	Impact					
	Reset External Pins to Default State	Execute Kernel	Reset All MMRs Except RSTSTA	Reset All Peripherals	Valid SRAM	RSTSTA After Reset Event
SWRST	Yes ¹ /No ²	Yes	Yes/No ²	Yes/No ²	Yes/No ³	RSTSTA[3] = 1
WDRST	Yes/No ²	Yes	Yes/No ²	Yes/No ²	Yes/No ³	RSTSTA[2] = 1
External Reset Pin	Yes ¹	Yes	Yes	Yes	Yes/No ³	RSTSTA[1] = 1
POR	Yes ¹	Yes	Yes	Yes	No	RSTSTA[0] = 1

¹ P2.2 returns to its default state, that is, POR output. It is low only in the case of a POR event; in all other cases, it remains high.

² GPIOs, PLA, and analog peripherals have the option of retaining their state during a watchdog or software reset.

³ RAM is not valid in the case of a reset following an MDIO download.

REGISTER SUMMARY: RESET

Table 65. Reset Register Summary

Address	Name	Description	Reset	RW

Table 66. Bit Descriptions for RSTSTA

Bits	Bit Name	Description	Reset	Access
[15:4]	RESERVED		0x0	R
3	SWRST	Software reset. Software reset. Set automatically to 1 when the Cortex-M3 system reset is generated. Cleared by writing 1 to the bit.	0x0	RW1C
2	WDRST	Watchdog timeout. Set automatically to 1 when a watchdog timeout occurs. Cleared by writing 1 to the bit.	0x0	RW1C
1	EXTRST	External reset. Set automatically to 1 when an external reset occurs. Cleared by writing 1 to the bit.	0x0	RW1C
0	POR	Power-on reset. Set automatically when a power-on reset occurs. Cleared by writing one to the bit.	0x0	RW1C

Reset Configuration Register

Address: 0x40002408, Reset: 0x0000, Name: RSTCFG

Table 67. Bit Descriptions for RSTCFG

Bits	Bit Name	Description	Reset	Access
0	GPIO_PLA_RETAIN	GPIO/PLA retain their status after WDT and software reset. 1: GPIO/PLA don't retain status after watchdog or software reset. 0: GPIO/PLA retain status after watchdog or software reset	0x0	RW

Key Protection for RSTCFG Register

Address: 0x4000240C, Reset: 0x0000, Name: RSTKEY

Table 68. Bit Descriptions for RSTKEY

Bits	Bit Name	Description	Reset	Access
[15:0]	RSTKEY	Reset configuration key register. The RSTCFG register is key-protected. Two writes to the key are necessary to change the value in the RSTCFG register. First 0x2009, then 0x0426. The RSTCFG register should then be written. A write to any other register on the APB bus before writing to RSTCFG will return the protection to the lock state.	0x0	RW

LV Die Reset Configuration Register

Address: 0x40082C34, Reset: 0x0000, Name: LVRST

Table 69. Bit Descriptions for LVRST

Bits	Bit Name	Description	Reset	Access
[15:1]	RESERVED		0x0	R
0	RETAIN	LV retains status after WDT and software reset. 0: LV die retains status after watchdog or software reset. 1: LV die does not retain status after watchdog or software reset.	0x0	RW

DMA CONTROLLER

DMA FEATURES

- 14 dedicated and independent DMA channels.
- Two programmable priority levels for each DMA channel.
 - Each priority level arbitrates using a fixed priority that is determined by the DMA channel number.
 - Channels with lower numbers have higher priority. For example, SPI0 transmit has the highest priority, and the next highest is the SPI0 receive.
- Each DMA channel can access a primary and/or alternate channel control structure.
- Supports multiple DMA transfer types.
 - Memory to memory.
 - Memory to peripheral.
 - Peripheral to memory.

DMA OVERVIEW

Direct memory access (DMA) is used to provide high speed data transfer between peripherals and memory. Data can be moved quickly by DMA without any processor actions. This keeps processor resources free for other operations.

The DMA controller has 14 channels in total. The 14 channels used are dedicated to managing DMA requests from specific peripherals. Channels are assigned as shown in Table 70.

Table 70. DMA Channel Assignment

Channel	Peripheral
0	SPI0 Tx
1	SPI0 Rx
2	SPI1 Tx
3	SPI1 Rx
4	UART Tx
5	UART Rx
6	I2C0 slave Tx
7	I2C0 slave Rx
8	I2C0 master
9	I2C1 slave Tx
10	I2C1 slave Rx
11	I2C1 master
12	ADC
13	Flash

The channels are connected to dedicated hardware DMA requests; a software trigger is also supported on each channel. This configuration is done by software. Each DMA channel has a programmable priority level—default or high. Within a priority level, arbitration is performed using a fixed priority that is determined by the DMA channel number. Channels with lower numbers have higher priority. For example, SPI0 transmit has the highest priority, and the next highest is the SPI0 receive.

The DMA controller supports multiple DMA transfer data widths—independent source and destination transfer size (byte, half word, and word). Source/destination addresses must be aligned on the data size.

The DMA controller supports peripheral-to-memory, memory-to-peripheral, and memory-to-memory transfers and access to flash or SRAM as source and destination.

DMA OPERATION

The DMA controller performs direct memory transfer by sharing the system bus with the Cortex-M3 processor. The DMA request may stall the processor access to the system bus for some bus cycles when the processor and DMA are targeting the same destination (memory or peripheral).

DMA INTERRUPTS

An interrupt can be produced for each DMA channel when a transfer is complete. Separate interrupt enable bits are available in the NVIC for each of the DMA channels.

The DMA controller fetches channel control data structures located in the SRAM memory to perform data transfers. When enabled to use DMA operation, the DMA-capable peripherals request the DMA controller for transfer. At the end of the programmed number of DMA transfers for a channel, the DMA controller generates an interrupt corresponding to that channel. This interrupt indicates the completion of the DMA transfer.

DMA PRIORITY

The priority of a channel is determined by its number and priority level. Each channel can have two priority levels: default or high. All channels at high priority level have higher priority than all channels at default priority level. At the same priority level, a channel with a lower channel number has higher priority than a channel with a higher channel number. The DMA channel priority levels can be changed by writing into the appropriate bit in the DMAPRISET register.

CHANNEL CONTROL DATA STRUCTURE

Every channel has two control data structures associated with it: primary data structure and an alternate data structure. For simple transfer modes, the DMA controller uses either the primary or the alternate data structure. For more complex data transfer modes, such as ping-pong or scatter-gather, the DMA controller uses both the primary and alternate data structures. Each control data structure (primary or alternate) occupies four 32-bit locations in the memory as shown in Table 71. The entire channel control data structure is shown in Table 72.

Table 71. Channel Control Data Structure

Offset	Name	Description
0x00	SRC_END_PTR	Source end pointer
0x04	DST_END_PTR	Destination end pointer
0x08	CHNL_CFG	Control data configuration
0x0C	Reserved	Reserved

Before the controller can perform a DMA transfer, the data structure related to the DMA channel must be programmed at the designated location in system memory, SRAM.

- The source end pointer memory location contains the end address of the source data.
- The destination end pointer memory location contains the end address of the destination data.
- The control data configuration memory location contains the channel configuration control data.

The programming determines the source and destination data size, number of transfers, and the number of arbitrations.

Table 72. Memory Map of Primary and Alternate DMA Structures

Channel	Primary Structures		Alternate Structures	
	Register Description	Offset Address	Register Description	Offset Address
Channel 13	Reserved; set to 0	0x0DC	Reserved; set to 0	0x1DC
	Control	0x0D8	Control	0x1D8
	Destination end pointer	0x0D4	Destination end pointer	0x1D4
	Source end pointer	0x0D0	Source end pointer	0x1D0
...
Channel 1	Reserved; set to 0	0x01C	Reserved; set to 0	0x11C
	Control	0x018	Control	0x118
	Destination end pointer	0x014	Destination end pointer	0x114
	Source end pointer	0x010	Source end pointer	0x110
Channel 0	Reserved; set to 0	0x00C	Reserved; set to 0	0x10C
	Control	0x008	Control	0x108
	Destination end pointer	0x004	Destination end pointer	0x104
	Source end pointer	0x000	Source end pointer	0x100

The user must define DMA structures in their source code as shown in the examples in the Example Code: Define DMA Structures section. After the structure has been defined, its start address must be assigned to the DMA base address pointer register, DMAPDBPTR. Each register for each DMA channel is then at the offset address, as specified in Table 72, plus the value in the DMAPDBPTR register.

Example Code: Define DMA Structures

To define DMA structures,

```
memset(dmaChanDesc, 0x0, sizeof(dmaChanDesc)); // Set up the DMA base address pointer register.
uiBasPtr = (unsigned int)&dmaChanDesc; // Set up the DMA base pointer.
pADI_DMA->DMACFG = 1; // Enable DMA controller
pADI_DMA->DMAPDBPTR = uiBasPtr;
```

CONTROL DATA CONFIGURATION

For each DMA transfer, the CHNL_CFG memory location provides the control information for the DMA transfer to the controller.

Table 73. Control Data Configuration

Bits	Name	Description		
[31:30]	DST_INC	Destination address increment. The address increment depends on the source data width as follows:		
		Source Data Width	DST_INC	Destination Address Increment
		Byte	00	Byte.
			01	Half word.
			10	Word.
			11	No increment. Address remains set to the value that the DST_END_PTR memory location contains.
		Half Word	00	Reserved.
			01	Half word.
			10	Word.
			11	No increment. Address remains set to the value that the DST_END_PTR memory location contains.
		Word	00	Reserved.
			01	Reserved.
10	Word.			
11	No increment. Address remains set to the value that the DST_END_PTR memory location contains.			
[29:28]	Reserved	Undefined. Write as 0.		
[27:26]	SRC_INC	Source address increment. The address increment depends on the source data width as follows:		
		Source Data Width	DST_INC	Source Address Increment
		Byte	00	Byte.
			01	Half word.
			10	Word.
			11	No increment. Address remains set to the value that the SRC_END_PTR memory location contains.
		Half Word	00	Reserved.
			01	Half word.
			10	Word.
			11	No increment. Address remains set to the value that the SRC_END_PTR memory location contains.
		Word	00	Reserved.
			01	Reserved.
10	Word.			
11	No increment. Address remains set to the value that the SRC_END_PTR memory location contains.			

Bits	Name	Description
[25:24]	SRC_SIZE	Size of the source data. 00: byte. 01: half word. 10: word. 11: Reserved.
[23:18]	Reserved	Undefined. Write as 0.
[17:14]	R_POWER	Set these bits to control how many DMA transfers can occur before the controller re-arbitrates. Must be set to 0000 for all DMA transfers involving peripherals. Note that the operation of the DMA is indeterminate if a value other than 0000 is programmed in this location for DMA transfers involving peripherals.
[13:4]	N_MINUS_1	The number of configured transfers minus 1 for that channel. The 10-bit value indicates the number of DMA transfers (not the total number of bytes) minus one. The possible values are 0x000: 1 DMA transfer 0x001: 2 DMA transfers 0x002: 3 DMA transfers ... 0x3FF: 1024 DMA transfers.
3	Reserved	Undefined. Write as 0.
[2:0]	CYCLE_CTRL	The transfer types of the DMA cycle. 000: Stop (invalid) 001: Basic 010: Autorequest 011: Ping-pong 100: Memory scatter-gather primary 101: Memory scatter-gather alternate 110: Peripheral scatter-gather primary 111: Peripheral scatter-gather alternate

During the DMA transfer process, but before arbitration, CHNL_CFG is written back to system memory with the N_MINUS_1 field changed to reflect the number of transfers yet to be completed.

When the DMA cycle is complete, the CYCLE_CTRL bits are made invalid to indicate the completion of the transfer.

DMA TRANSFER TYPES (CHNL_CFG[2:0])

The DMA controller supports five types of DMA transfers. The various types are selected by programming the appropriate values into the CYCLE_CTRL bits (Bits[2:0]) in the CHNL_CFG location of the control data structure.

Invalid (CHNL_CFG[2:0] = 000)

This means no DMA transfer is enabled for the channel. After the controller completes a DMA cycle, it sets the cycle type to invalid to prevent it from repeating the same DMA cycle.

Basic (CHNL_CFG[2:0] = 001)

In this mode, the controller can be configured to use either the primary or alternate data structure. The peripheral must present a request for every data transfer. After the channel is enabled, when the controller receives a request, it performs the following operations:

1. The controller performs a transfer. If the number of transfers remaining is zero, the flow continues at Step 3.
2. The controller arbitrates
 - a. If a higher priority channel is requesting service, then the controller services that channel.
 - b. If the peripheral or software signals a request to the controller, then it continues at Step 1.
3. At the end of the transfer, the controller generates the corresponding DMA channel interrupt in the NVIC

Autorequest (CHNL_CFG[2:0] = 010)

When the controller operates in this mode, it is only necessary for the controller to receive a single request to enable it to complete the entire DMA cycle. This allows a large data transfer to occur without significantly increasing the latency for servicing higher priority requests or requiring multiple requests from the processor or peripheral. This mode is very useful for a memory-to-memory copy application.

Autorequest is not suitable for peripheral use—except for the ADC sequencer mode, where a number of peripheral operations need to be completed.

In this mode, the controller can be configured to use either the primary or alternate data structure. After the channel is enabled, when the controller receives a request, it performs the following operations:

1. The controller performs $\min(2^{R_POWER}, N)$ transfers for the channel, where R_POWER is Bits[17:14] of the control data configuration register and N is the number of transfers. If the number of transfers remaining is zero, the flow continues at Step 3.
2. A request for the channel is automatically generated. The controller arbitrates. If the channel has the highest priority, the DMA cycle continues at Step 1.
3. At the end of the transfer, the controller generates an interrupt for the corresponding DMA channel.

Ping-Pong (CHNL_CFG[2:0] = 011)

In ping-pong mode, the controller performs a DMA cycle using one of the data structures and then performs a DMA cycle using the other data structure. The controller continues to alternate between using the primary and alternate data structures until it either reads a data structure that is invalid or the host processor disables the channel.

This mode is useful for transferring data from peripheral to memory using different buffers in the memory. In a typical application, the host must configure both primary and alternate data structures before starting the transfer. As the transfer progresses, the host can subsequently configure primary or alternate control data structures in the interrupt service routine when the corresponding transfer ends.

The DMA controller interrupts the processor after the completion of transfers associated with each control data structure. The individual transfers using either the primary or alternate control data structure work exactly the same as a basic DMA transfer.

Memory Scatter-Gather (CHNL_CFG[2:0] = 100 or 101)

In memory scatter-gather mode, the controller must be configured to use both the primary and alternate data structures. The controller uses the primary data structure to program the control configuration for the alternate data structure. The alternate data structure is used for actual data transfers, which are similar to an autorequest DMA transfer. The controller arbitrates after every primary transfer. The controller needs only one request to complete the entire transfer. This mode is used when performing multiple memory-to-memory copy tasks. The processor can configure all of the tasks simultaneously and does not need to intervene in between each task. The controller generates the corresponding DMA channel interrupt in the NVIC when the entire scatter-gather transaction completes using a basic cycle.

In this mode, the controller receives an initial request and then performs four DMA transfers using the primary data structure to program the control structure of the alternate data structure. After this transfer completes, the controller starts a DMA cycle using the alternate data structure. After the cycle completes, the controller performs another four DMA transfers using the primary data structure. The controller continues to alternate between using the primary and alternate data structures until either the processor configures the alternate data structure for a basic cycle or the DMA reads an invalid data structure.

Table 74 lists the fields of the CHNL_CFG memory location for the primary data structure, which must be programmed with constant values for the memory scatter-gather mode.

Table 74. CHNL_CFG for Primary Data Structure in Memory Scatter-Gather Mode, CHNL_CFG[2:0] = 100

Bits	Name	Description
31:30	DST_INC	10: Configures the controller to use word increments for the address.
29:28	Reserved	Undefined. Write as 0.
27:26	SRC_INC	10: Configures the controller to use word increments for the address.
25:24	SRC_SIZE	10: Configures the controller to use word transfers.
23:18	Reserved	Undefined. Write as 0.
17:14	R_POWER	0010: Indicates that the DMA controller is to perform four transfers.
13: 4	N_MINUS_1	Configures the controller to perform N DMA transfers, where N is a multiple of 4.
3	Reserved	Undefined. Write as 0.
2:0	CYCLE_CTRL	100: Configures the controller to perform a memory scatter-gather DMA cycle.

Peripheral Scatter-Gather (CHNL_CFG[2:0] = 110 or 111)

In peripheral scatter-gather mode, the controller must be configured to use both the primary and alternate data structure. The controller uses the primary data structure to program the control structure of the alternate data structure. The alternate data structure is used for actual data transfers, and each transfer takes place using the alternate data structure with a basic DMA transfer. The controller does not arbitrate after every primary transfer. This mode is used when there are multiple peripheral-to-memory DMA tasks to be performed. The Cortex-M3 can configure all of the tasks simultaneously and does not need to intervene in between each task. This is very similar to memory scatter-gather mode except for arbitration and request requirements. The controller generates the corresponding DMA channel interrupt in the NVIC when the entire scatter-gather transaction completes using a basic cycle.

In peripheral scatter-gather mode, the controller receives an initial request from a peripheral and then performs four DMA transfers using the primary data structure to program the alternate control data structure. The controller then immediately starts a DMA cycle using the alternate data structure without re-arbitrating.

After this cycle completes, the controller re-arbitrates, and if it receives a request from the peripheral that has the highest priority, it performs another four DMA transfers using the primary data structure. It then immediately starts a DMA cycle using the alternate data structure without re-arbitrating. The controller continues to alternate between using the primary and alternate data structures until either the processor configures the alternate data structure for a basic cycle or the DMA reads an invalid data structure.

Table 75 lists the fields of the CHNL_CFG memory location for the primary data structure, which must be programmed with constant values for the peripheral scatter-gather mode.

Table 75. CHNL_CFG for Primary Data Structure in Peripheral Scatter-Gather Mode, CHNL_CFG[2:0] = 110

Bits	Name	Description
31:30	DST_INC	10: Configures the controller to use word increments for the address.
29:28	Reserved	Undefined. Write as 0.
27:26	SRC_INC	10: Configures the controller to use word increments for the address.
25:24	SRC_SIZE	10: Configures the controller to use word transfers.
23:18	Reserved	Undefined. Write as 0.
17:14	R_POWER	0010: Indicates that the DMA controller performed four transfers without re-arbitration.
13: 4	N_MINUS_1	Configures the controller to perform N DMA transfers, where N is a multiple of 4.
3	Reserved	Undefined. Write as 0.
2:0	CYCLE_CTRL	110: Configures the controller to perform a memory scatter-gather DMA cycle.

ADDRESS CALCULATION

The DMA controller calculates the source read address based on the content of SRC_END_PTR, the source address increment setting in CHNL_CFG, and the current value of N_MINUS_1 (CHNL_CFG[13:4]).

Similarly, the destination write address is calculated based on the content of DST_END_PTR, the destination address increment setting in CHNL_CFG, and the current value of N_MINUS_1 (CHNL_CFG[13:4]).

Source Read Address = SRC_END_PTR - (N_MINUS_1 << (SRC_INC)) for SRC_INC = 0, 1, 2

Source Read Address = SRC_END_PTR for SRC_INC = 3

Destination Write Address = DST_END_PTR - (N_MINUS_1 << (DST_INC)) for DST_INC = 0, 1, 2

Destination Write Address = DST_END_PTR for DST_INC = 3

where *N_MINUS_1* is the number of configured transfers minus 1 for that channel.

REGISTER SUMMARY: DMA

Table 76. DMA Register Summary

Address	Name	Description	Reset	RW
0x40010000	DMASTA	DMA Status	0x000F0000	R
0x40010004	DMACFG	DMA Configuration	0x00000000	W
0x40010008	DMAPDBPTR	DMA channel primary control data base pointer	0x00000000	RW

DMA Channel Primary Control Data Base Pointer Register

Address: 0x40010008, Reset: 0x00000000, Name: DMAPDBPTR

The DMAPDBPTR register must be programmed to point to the primary channel control base pointer in the system memory. The amount of system memory that must be assigned to the DMA controller depends on the number of DMA channels used and whether the alternate channel control data structure is used. This register cannot be read when the DMA controller is in the reset state.

Table 79. Bit Descriptions for DMAPDBPTR

Bits	Bit Name	Description	Reset	Access
[31:0]	CTRLBASEPTR	Pointer to the base address of the primary data structure. 5 + log(2) M LSBs are reserved and must be written 0. M is number of channels.	0x0	RW

DMA Channel Alternate Control Data Base Pointer Register

Address: 0x4001000C, Reset: 0x00000100, Name: DMAADBPTR

The DMAADBPTR read-only register returns the base address of the alternate channel control data structure. This register removes the necessity for application software to calculate the base address of the alternate data structure. This register cannot be read when the DMA controller is in the reset state.

Table 80. Bit Descriptions for DMAADBPTR

Bits	Bit Name	Description	Reset	Access
[31:0]	ALTCBPTR	Base address of the alternate data structure.	0x100	R

DMA Channel Software Request Register

Address: 0x40010014, Reset: 0x00000000, Name: DMASWREQ

The DMASWREQ register enables the generation of software DMA request. Each bit of the register represents the corresponding channel number in the DMA controller. M is the number of DMA channels

Table 81. Bit Descriptions for DMASWREQ

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved.	0x0	W
[13:0]	CHSWREQ	Generate software request. Set the appropriate bit to generate a software DMA request on the corresponding DMA channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Written: Bit [C] = 0, Does not create a DMA request for channel C. Bit [C] = 1, Generates a DMA request for channel C. These bits are automatically cleared by the hardware after the corresponding software request completes.	0x0	W

DMA Channel Request Mask Set Register

Address: 0x40010020, Reset: 0x00000000, Name: DMARMSKSET

Table 82. Bit Descriptions for DMARMSKSET

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Reserved, reads back 0.	0x0	R
[13:0]	CHREQMSET	Mask requests from DMA channels. This register disables DMA requests from peripherals. Each bit of the register represents the corresponding channel number in the DMA controller. Set the appropriate bit to mask the request from the corresponding DMA channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Read: Bit [C] = 0, Requests are enabled for channel C. Bit [C] = 1, Requests are disabled for channel C. When Written: Bit [C] = 0, No effect. Use the DMARMSKCLR register to enable DMA requests. Bit [C] = 1, Disables peripheral associated with channel C from generating DMA requests.	0x0	RW

DMA Channel Request Mask Clear Register

Address: 0x40010024, Reset: 0x00000000, Name: DMARMSKCLR

Table 83. Bit Descriptions for DMARMSKCLR

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved.	0x0	R
[13:0]	CHREQMCLR	Clear REQ_MASK_SET bits in DMARMSKSET. This register enables DMA requests from peripherals by clearing the mask set in DMARMSKSET register. Each bit of the register represents the corresponding channel number in the DMA controller. Set the appropriate bit to clear the corresponding REQ_MASK_SET bit in DMARMSKSET register. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Written: Bit [C] = 0, No effect. Use the DMARMSKSET register to disable DMA requests. Bit [C] = 1, Enables peripheral associated with channel C to generate DMA requests.	0x0	W

DMA Channel Enable Set Register

Address: 0x40010028, Reset: 0x00000000, Name: DMAENSET

Table 84. Bit Descriptions for DMAENSET

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved.	0x0	R
[13:0]	CHENSET	Enable DMA channels. This register allows for the enabling of DMA channels. Reading the register returns the enable status of the channels. Each bit of the register represents the corresponding channel number in the DMA controller. Set the appropriate bit to enable the corresponding channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Read: Bit [C] = 0, Channel C is disabled. Bit [C] = 1, Channel C is enabled.	0x0	RW

Bits	Bit Name	Description	Reset	Access
		When Written: Bit [C] = 0, No effect. Use the DMAENCLR register to disable the channel. Bit [C] = 1, Enables channel C.		

DMA Channel Enable Clear Register

Address: 0x4001002C, Reset: 0x00000000, Name: DMAENCLR

Table 85. Bit Descriptions for DMAENCLR

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHENCLR	Disable DMA channels. This register allows for the disabling of DMA channels. Reading the register returns the enable status of the channels. Each bit of the register represents the corresponding channel number in the DMA controller. Note: The controller disables a channel automatically, by setting the appropriate bit, when it completes the DMA cycle. Set the appropriate bit to disable the corresponding channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Written: Bit [C] = 0, No effect. Use the DMAENSET register to enable the channel. Bit [C] = 1, Disables channel C.	0x0	W

DMA Channel Primary-Alternate Set Register

Address: 0x40010030, Reset: 0x00000000, Name: DMAALTSET

The DMAALTSET register enables the user to configure the appropriate DMA channel to use the alternate control data structure. Reading the register returns the status of which data structure is in use for the corresponding DMA channel. Each bit of the register represents the corresponding channel number in the DMA controller.

Note: The DMA controller sets/clears these bits automatically as necessary for ping-pong, memory scatter-gather and peripheral scatter-gather transfers.

Table 86. Bit Descriptions for DMAALTSET

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHPRIALTSET	Control struct status / select alt struct. Returns the channel control data structure status, or selects the alternate data structure for the corresponding DMA channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Read: Bit [C] = 0, DMA channel C is using the primary data structure. Bit [C] = 1, DMA channel C is using the alternate data structure. When Written: Bit [C] = 0, No effect. Use the DMAALTCLR register to set bit [C] to 0. Bit [C] = 1, Selects the alternate data structure for channel C.	0x0	RW

DMA Channel Primary-Alternate Clear Register

Address: 0x40010034, Reset: 0x00000000, Name: DMAALTCLR

The DMAALTCLR write-only register enables the user to configure the appropriate DMA channel to use the primary control data structure. Each bit of the register represents the corresponding channel number in the DMA controller.

Note: The DMA controller sets/clears these bits automatically as necessary for ping-pong, memory scatter-gather and peripheral scatter-gather transfers.

Table 87. Bit Descriptions for DMAALTCLR

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHPRIALTCLR	Select primary data struct. Set the appropriate bit to select the primary data structure for the corresponding DMA channel. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Written: Bit [C] = 0, No effect. Use the DMAALTSET register to select the alternate data structure. Bit [C] = 1, Selects the primary data structure for channel C.	0x0	W

DMA Channel Priority Set Register

Address: 0x40010038, Reset: 0x00000000, Name: DMAPRISET

Table 88. Bit Descriptions for DMAPRISET

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHPRISET	Configure channel for high priority. This register enables the user to you to configure a DMA channel to use the high priority level. Reading the register returns the status of the channel priority mask. Each bit of the register represents the corresponding channel number in the DMA controller. Returns the channel priority mask status, or sets the channel priority to high. Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1 When Read: Bit [C] = 0, DMA channel C is using the default priority level. Bit [C] = 1, DMA channel C is using a high priority level. When Written: Bit [C] = 0, No effect. Use the DMAPRICLR register to set channel C to the default priority level. Bit [C] = 1, Channel C uses the high priority level.	0x0	RW

DMA Channel Priority Clear Register

Address: 0x4001003C, Reset: 0x00000000, Name: DMAPRICLR

Table 89. Bit Descriptions for DMAPRICLR

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHPRICLR	Configure channel for default priority level. The DMAPRICLR write-only register enables the user to configure a DMA channel to use the default priority level. Each bit of the register represents the corresponding channel number in the DMA controller. Set the appropriate bit to select the default priority level for the specified DMA channel. Bit 0 corresponds to DMA channel and bit M-1 corresponds to DMA channel M-1 When Written: Bit [C] = 0, No effect. Use the DMAPRISET register to set channel C to the high priority level. Bit [C] = 1, Channel C uses the default priority level.	0x0	W

DMA Per Channel Bus Error Register

Address: 0x4001004C, Reset: 0x00000000, Name: DMAERRCLR

Table 90. Bit Descriptions for DMAERRCLR

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	ERRCLR	<p>Bus error status. This register is used to read and clear the DMA bus error status. The error status is set if the controller encountered a bus error while performing a transfer or when it reads an invalid descriptor (whose cycle control is 3'b000). If a bus error occurs or invalid cycle control is read on a channel, that channel is automatically disabled by the controller. The other channels are unaffected. Write one to clear bits.</p> <p>Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1</p> <p>When Read:</p> <p>Bit [C] = 0 – No bus_error/invalid cycle control occurred.</p> <p>Bit [C] = 1 – A bus_error/invalid cycle control is pending.</p> <p>When Written:</p> <p>Bit [C] = 0 – No effect.</p> <p>Bit [C] = 1 – Bit is cleared.</p>	0x0	RW1C

DMA Channel Bytes Swap Enable Set Register

Address: 0x40010800, Reset: 0x00000000, Name: DMABSSET

Table 91. Bit Descriptions for DMABSSET

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHBSWAPSET	<p>Byte swap status. This register is used to configure a DMA channel to use byte. Each bit of the register represents the corresponding channel number in the DMA controller.</p> <p>Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1</p> <p>When Read:</p> <p>Bit [C] = 0, Channel C Byte Swap is disabled.</p> <p>Bit [C] = 1, Channel C Byte Swap is enabled.</p> <p>When Written:</p> <p>Bit [C] = 0, No effect. Use the DMABSCLR register to disable byte swap on channel C</p> <p>Bit [C] = 1, Enables Byte Swap on channel C.</p>	0x0	RW

DMA Channel Bytes Swap Enable Clear Register

Address: 0x40010804, Reset: 0x00000000, Name: DMABSCLR

Table 92. Bit Descriptions for DMABSCLR

[31:14]	RESERVED	Reserved. Undefined.	0x0	R
[13:0]	CHBSWAPCLR	<p>Disable byte swap. The DMABSCLR write-only register enables the user to configure a DMA channel to not use byte swapping and use the default operation. Each bit of the register represents the corresponding channel number in the DMA controller.</p> <p>Bit 0 corresponds to DMA channel 0, bit M-1 corresponds to DMA channel M-1</p> <p>When Written:</p> <p>Bit [C] = 0, No effect. Use the DMABSSET register to enable byte swap on channel C.</p> <p>Bit [C] = 1, Disables Byte Swap on channel C.</p>	0x0	W

FLASH CONTROLLER

FLASH CONTROLLER FEATURES

- 256 kB Flash/EE memory in two blocks of 128 kB each (Flash 0 and Flash 1).
- 4 kB information space, which contains factory code.
- Supports flash block switching for MDIO. For MDIO specific details, see the MDIO section.

FLASH CONTROLLER OVERVIEW

- Supports read on one flash block and erase/write operation on the other block.
- Peripheral DMA support for flash keyhole-based write.
- Kernel present in information space.
- Supports buffered read, executing code from a 64-bit read while fetching the next 64 bits.
- 32-bit interface for MMR access.
- Flash program, erase timing controlled via the fixed 16 MHz reference clock.
- Keyhole open for access, command fail, command complete status bits.
- Cache provided to speed up execution.

Commands

- Write command: 64 bits per write.
- Page erase commands.
- Mass erase commands for each flash block.
- Generation of signatures for single or multiple pages.
- Command abort supported. This is possible by writing to command MMR or by a system interrupt.
- Keys required for running commands such as a mass erase and the test commands.

Protection, Integrity

- Write/read protection for user space.
- Read and write protection for information space.
- Ability to lock the SW-DP interface.
- Automatic signature check of information space on reset.
- User signature check of user space and information space.

FLASH CONTROLLER OPERATION

User Space

Flash blocks—Flash 0 and Flash 1—of 128 kB each are available for user code and data. Generally, this can be considered to be a 256 kB block, from 0 to 0x3FFFF, except that it is not possible to execute from one flash block while erasing or writing parts of the same block.

The top 24 bytes of user space in each flash block are reserved for a signature, the user write protection pattern, and the user flash failure analysis key (UserFaaKey).

If a user tries to read a portion of memory that is not available, a bus error is returned. If a user tries to write via keyhole access to a portion of memory that is not available, an appropriate error flag is set.

Information Space

Information space of Flash 0 and Flash 1 is located at Address 0x40000 to Address 0x40FFF and is divided up between kernel space, test space, and calibration space. Information space is reserved for use by Analog Devices. Upon a reset, the hardware forces the part to execute from the start of information space to copy calibration and configuration values to appropriate MMRs. When the kernel completes, it passes code execution to the start of user code.

The hardware automatically checks the integrity of the kernel after reset. In the event of a failure, FEESTA[13] is set and user code cannot run. This bit can only be read via a serial wire read if the serial wire interface is enabled.

The kernel code cannot be accessed by the user. A user can read 16 bytes of Flash 0 information space at Address 0x407E8 to Address 0x407F7. These locations contain ManfID0, ManfID1, and the next eight bytes, which are reserved. ManfID0 and ManfID1 contain traceability information to uniquely identify every part sold.

The top two bytes at 0x407f4 identifies the silicon version and the kernel revision. The first hexadecimal digit in the two bytes translates to the silicon revision, with 0x1 being the first silicon and each future revision incrementing by 1. The next two hexadecimal digits are the ASCII encoded version of the kernel. Prerelease versions start at Y; after release, this will change to the ASCII character 0 and increment upwards if any changes are necessary. The fourth hexadecimal digit represents the kernel minor revision. This starts at 0xE and is decremented for every minor change to the kernel. For example, 0x159A translates as follows: 1 indicates first silicon, 59 indicates kernel revision Y in ASCII code, and A indicates minor revision A.

There are also hardware registers that identify the version of each silicon die. For more information, see the Silicon Identification section.

Keys

The value 0xF123F456 must be written to the FEEKEY register to run certain user commands, to write to certain locations in flash, or to enable write access to the user setup register (FEECON1).

FLASH MEMORY OPERATION

Keyhole Access

Writing to flash is through keyhole access.

Keyhole access consists of

- Flash address
- Flash data MMR
- Command MMR

Top of Flash Blocks

The top six words of each flash block have special functionality, as listed in Figure 13 and Figure 14. Therefore, normal code or data cannot be placed in this space.

117B-114

Figure 14. Uppermost Page in User Flash 0 Space

Writing to Flash

Each write programs 64 bits of data.

To write to a flash location, the following sequence is required:

1. Write the address of the flash location to FEEFLADR.
2. Write the 64 bits of data to FEEFLDATA0 and FEEFLDATA1.
3. Write the write command to FEECMD.

After the write command is given, the controller writes to flash. CMDDONE (FEESTA[2]) indicates that the command is completed.

The following should also be noted:

- A 64-bit location can be written to only once unless it is erased again.

Erasing Flash

User code can call three flash erase commands:

- MASSERASE0: This command erases the entire user Flash 0 memory. After entering the user protection key into FEEKEY, write the MASSERASE0 command to FEECMD.
- MASSERASE1: This command erases the entire user Flash 1 memory. After entering the user protection key into FEEKEY, write the MASSERASE1 command to FEECMD.
- PAGEERASE: This command erases 2 kB of flash. The page is selected by FEEADR1L. After entering the user protection key into FEEKEY, load FEEADR1L with the page address to be erased. Finally, write the page erase command to FEECMD. CMDDONE (FEESTA[2]) indicates that the command is completed.

During a page or mass erase sequence, the flash controller and flash block consume extra current for the duration of the flash erase sequence.

Signature

The signature is used to check the integrity of the flash device. The signature is calculated from the lowest 32-bit halfword to the highest 32-bit halfword in the selected block. The signature is a 24-bit CRC with the following polynomial:

$$x^{24} + x^{23} + x^6 + x^5 + x + 1$$

The data is pushed into the CRC polynomial until the specified end address is reached. A block can be a single page or multiple pages. The hardware assumes that the signature for a block is stored in the upper eight bytes of the most significant page of a block; therefore, these 64 bits are not included when generating the signature. While the signature is being computed for a particular flash, all other accesses to the same flash are stalled. For a 128 kB block, 32k CPU clock cycles are required to calculate the signature.

Note that FEEADR0/FEEADR1 addresses are byte addresses but only pages need to be identified because the lower 11 bits are ignored by the hardware.

Flash Protection

There are three types of protection implemented:

- Key protection
- Read protection
- Write protection

Flash Protection: Key Protection

Some of the flash controller MMRs are key-protected to avoid accidental writes to these MMRs.

The user key is 0xF123F456. This key must be entered to run certain user commands, to write to certain locations in flash, or to enable write access to FEECON1. Once entered, the key remains asserted unless a command is written to FEECMD. When the command starts, the key clears automatically. If this key is entered to enable write access to FEECON1 or to enable writes to certain locations in flash, it needs to be cleared by user code afterwards. To clear the key, write any value other than 0xF123F456 to FEEKEY.

Flash Protection: User Read Protection

User space read protection is provided by disabling serial wire access. A user can disable serial wire debug access by writing 0 to Bit 0 of FEECON1. Serial wire debug access is disabled while the kernel is running; otherwise, serial wire debug access may prevent the kernel from running to completion. When the kernel exits to user code, it enables serial wire access unless either of the keys at 0x3FFF4 or 0x1FFF4 is set to 0x0000003A. This means that the part is always read protected after either key is in place and that no debug access can occur.

Flash Protection: User Write Protection

User write protection is provided to prevent accidental writes to pages in user space and to protect blocks of user code when downloading extra code to flash. If a write or erase of a protected location is detected, the flash controller generates an interrupt if the command error/complete interrupt are enabled. The write protection for each block is stored near the top of each block. The top four bytes are for a signature, and the next eight bytes are reserved. The next 32-bit flash location contains the protection pattern, which is copied to FEEPRO0 and FEEPRO1 at startup, with each bit protecting a block of 4 kB of flash. If no protection is specified, protection can be set by writing to FEEPRO0 and FEEPRO1.

Flash Failure Analysis Key

It may be necessary to perform failure analysis on parts that are returned by a user even though read protection is enabled. A method has been provided to allow failure analysis of protected memory by a user flash failure analysis key (UserFaaKey).

The user must set the key as two 32-bit values near the top of each user flash block. Supplying this key to Analog Devices will allow access to user code for debug purposes. See Figure 13 and Figure 14 for details.

Flash Controller Abort

Commands (erase, sign, or mass verify) and writes can be aborted upon receipt of an interrupt, as listed in Table 53. Aborts are also possible by writing an abort command to the FEECMD register. However, if flash is being programmed and the routine controlling the programming is in flash, it is not possible to use the abort command to abort the cycle because instructions cannot be read. Therefore, the ability to abort a cycle on the assertion of any system interrupt is provided. The FEEAENx register is used to enable aborts upon receipt of an interrupt. Each bit in the FEEAENx registers corresponds to an interrupt listed in Table 53. Setting a bit in the FEEAENx register enables the corresponding interrupt to abort flash operations.

When a command or write is aborted via a system interrupt, FEESTA[5:4] indicates an abort (FEESTA[5:4] = 11).

Depending on the state that a write cycle is in when the abort asserts, the write cycle may or may not complete. If the write or erase cycle did not complete successfully, a fail status of aborted can be read in the status register.

If an immediate response to an interrupt is required during an erase or program cycle, the interrupt service routine and the interrupt vector table must be moved to SRAM or must be in the other flash block for the duration of the cycle.

If the DMA engine is set up to write a block of data to flash, an interrupt can be set up to abort the current write; however, the DMA engine starts the next write immediately. The interrupt causing the abort stays asserted so that there is a number of aborted write cycles in this case before the processor gains access to flash.

When an abort is triggered by an interrupt, all commands are repeatedly aborted until the appropriate FEEAENx bit is cleared or the interrupt source is cleared.

CPU Execution Speed from Flash

Every flash fetch takes three CPU cycles at 80 MHz (unless the customer chooses a slower clock speed).

Flash is organized to fetch 64 bits for every fetch.

Cortex-M3 instructions can be either 16 or 32 bits. Therefore, one 64-bit fetch can contain two, three, or four instructions.

If the 64 bits contain three or four instructions, there will be no problem because the new instructions have been fetched before the instructions from the previous fetch have completed.

If the 64 bits contain only two instructions, there is a lookahead buffer. If the 64 bits contain four instructions, the buffer starts filling earlier until the fetches are a full 64 bits ahead of the requirements. The result is that a problem only occurs if there are two or more 64-bit

fetches that contain two instructions without a fetch in between them that contains four instructions for the buffer to catch up. The worst case is if there is a long series of 32-bit instructions, in which case, there will be one extra cycle for every fetch, leading to a maximum loss of speed of 33%.

This lookahead buffer is not effective for branches where the CPU pipeline and the lookahead buffer must be restarted from empty.

By extensive analysis, it has been shown that the loss of performance for this scheme is about 8% for typical C code.

The average performance can, therefore, be assumed to be equivalent to a full speed system at 74 MHz. This is true if the code is not in cache. If the code is already in cache (see the Memory Cache section), the speed is 80 MHz. When executing from RAM, the speed is 80 MHz.

Memory Cache

A memory cache is provided on chip to speed up program execution. The instruction cache is configured and set up by default. If the user writes code to the flash, then the user should perform a chip reset to ensure that the old cached data is cleared and that the new code can be executed. If a chip reset is not possible, the following code can be used to clear the cache.

```
void FeeClrCache(void)
{
    unsigned long ulCACHESETUP = pADI_FEE->CACHESETUP;
    if ((ulCACHESETUP & 0x2) == 0x2)
    {
        pADI_FEE->CACHEKEY = 0xf123f456;
        pADI_FEE->CACHESETUP |= 0x1;
        while ((pADI_FEE->CACHESTAT & 0x1) == 0x1)
        { }
    }
    if ((ulCACHESETUP & 0x20000) == 0x20000)
    {
        pADI_FEE->CACHEKEY = 0xf123f456;
        pADI_FEE->CACHESETUP |= 0x10000;
        while ((pADI_FEE->CACHESTAT & 0x10000) == 0x10000)
        { }
    }
    pADI_FEE->CACHEKEY = 0xf123f456;
    pADI_FEE->CACHESETUP = ulCACHESETUP;
}
```

Most programming tools will clear the cache before downloading code to a device.

Flash DMA Support

Flash controller operations can be supported by DMA. This feature is software configurable. The two flash blocks are independent, meaning that you can continue executing from one block while programming another block. The DMA is very useful for this because the core only needs to initiate the write to flash, and then the DMA finishes executing the code in the background, triggering an interrupt when the operation is complete. The following code can be used for writing to flash using the DMA:

```
void FLASHDMAINIT(void)
{
    pADI_DMA->DMACFG = 0x1; // Enable DMA mode in DMA controller
    Dma_Init();
    NVIC_EnableIRQ(DMA_FLASH_IRQn); // Enable Flash DMA IRQ
    FLASHDMAWRITE(uxFlashData, 64);
    pADI_DMA->DMAENSET = 0x2000;
    pADI_FEE->FEEFLADR = uiAdr;
    pADI_FEE->FEEKEY = 0xF123F456;
```

```
pADI_FEE->FEECON1 |= (FEECON1_KHDMA_EN);    // Enable Flash DMA mode
}
```

```
void FLASHDMAWRITE (unsigned char * pucTX_DMA, unsigned int iNumVals)
{
  DmaDesc Desc;
  // Common configuration of all the descriptors used here
  Desc.ctrlCfg.Bits.cycle_ctrl = DMA_BASIC;
  desc.ctrlcfg.bits.next_useburst = 0x0;
  desc.ctrlcfg.bits.r_power = 1;
  desc.ctrlcfg.bits.src_prot_ctrl = 0x0;
  Desc.ctrlCfg.Bits.dst_prot_ctrl = 0x0;
  Desc.ctrlCfg.Bits.src_size = DMA_SIZE_WORD;
  Desc.ctrlCfg.Bits.dst_size = DMA_SIZE_WORD;
  // TX Primary Descriptor
  Desc.srcEndPtr = (unsigned int)(pucTX_DMA+ 4*(iNumVals - 0x1) );
  Desc.destEndPtr = (unsigned int)&(pADI_FEE->FEEFLDATA1);
  Desc.ctrlCfg.Bits.n_minus_1 = iNumVals - 0x1;
  Desc.ctrlCfg.Bits.src_inc = DMA_SRCINC_WORD;
  Desc.ctrlCfg.Bits.dst_inc = DMA_DSTINC_NO;
  *Dma_GetDescriptor(Flash_C) = Desc;
}
```

```
void DMA_Flsh_Int_Handler()
{
  pADI_FEE->FEEKEY = 0xF123F456;
  pADI_FEE->FEECON1 &= (~FEECON1_KHDMA_EN);    // Disable Flash DMA mode
  dma_done = 1;
}
```

Flash Controller Performance and Command Duration

All flash functions are slower than the CPU execution speed. The CPU Execution Speed from Flash section details the slight penalty of slower flash reads. All other flash operations are significantly slower, as detailed in Table 93.

Table 93. Typical Flash Execution Times

Operation	Time (Typical)	Comment
Write 64-bit location	75 μ s	
Mass erase one flash block	18 ms	
Page erase one page	18 ms	
Sign Flash 0/Flash 1 information space	33 μ s	512 cycles, 2 kB
Sign Flash 0/Flash 1 user space	2.1 ms	32k cycles, 128 kB

In general, these timings should be used as a guideline only, and software should use the flash status information or the interrupt system to detect when flash operations are complete. If one of the operations in Table 93 is executed in the same block as the block from which the CPU fetches instructions, the CPU stalls until the operation is complete.

REGISTER SUMMARY: FLASH CONTROLLER

Table 94. Flash Controller Register Summary

Address	Name	Description	Reset	RW
0x40018000	FEESTA	Status register	0x00000000	R
0x40018004	FEECON0	Command Control register: interrupt enable register	0x00000000	RW
0x40018008	FEECMD	Command register	0x00000000	RW
0x4001800C	FEEFLADR	Flash address key - hole register	0x00000000	RW
0x40018010	FEEFLDATA0	Flash Data register: key-hole interface lower 32 bits	0x00000000	RW
0x40018014	FEEFLDATA1	Flash Data register: key-hole interface upper 32 bits	0x00000000	RW
0x40018018	FEEADR0	Lower page address register	0x00000000	RW
0x4001801C	FEEADR1	Upper page address register	0x00000000	RW
0x40018020	FEEKEY	Key register	0x00000000	W
0x40018028	FEEPRO0	write protection register for Flash 0	0xFFFFFFFF	RW
0x4001802C	FEEPRO1	write protection register for Flash 1	0xFFFFFFFF	RW
0x40018034	FEEFESIG	Upper halfword of signature	0x0000000X	R
0x40018038	FEECON1	User Setup register	0x0000001X	RW
0x40018040	FEEWRADDRA	write abort address register	0x0000000X	R
0x40018048	FEEAEN0	Interrupt abort enable register. Interrupt 31 to Interrupt 0.	0x00000000	RW
0x4001804C	FEEAEN1	Interrupt abort enable register. Interrupt 54 to Interrupt 32.	0x00000000	RW
0x400180C0	CACHESTAT	Cache Status register	0xX	R
0x400180C4	CACHESETUP	Cache Setup register	0xX	RW
0x400180C8	CACHEKEY	Cache Key register	0xX	W

REGISTER DETAILS: FLASH CONTROLLER**Status Register**

Address: 0x40018000, Reset: 0x00000000, Name: FEESTA

Table 95. Bit Descriptions for FEESTA

Bits	Bit Name	Description	Reset	Access
[31:14]	RESERVED	Reserved		
13	SIGNERR	Information space signature check on reset error. After a reset, the flash controller automatically checks the Info space signature. If the signature check fails this bit will asserted. User can check if this bit is set via serial wire only. User code does not execute if this bit is set. The bit is cleared if the correct signature is programmed to the MS long word in information space.	0x0	R
[12:6]	RESERVED	Reserved. Always returns 0 when read.		
[5:4]	CMDRES	These two bits indicate the status of a command on completion or the status of a write. If multiple commands are executed or there are multiple writes without a read of the status register then the first error encountered is stored. Cleared to 0 when read. 00: Successful completion of a command or a write 01: Attempted signcheck, write or erase of a protected location 10: Read verify error. After an erase, the controller reads the corresponding word(s) to verify that the transaction completed successfully. If data read is not all 'F's, this is the resulting status. If the Sign command is executed and the resulting signature does not match the data in the upper 4 bytes of the upper page in a block then this is the resulting status. 11: Indicates that a command or a write was aborted by an abort command or a system interrupt has caused an abort	0x0	RC

Bits	Bit Name	Description	Reset	Access
3	WRALMOSTDONE	Write almost Complete – key-hole registers open for access. This bit flags the earliest point at which the flash controller data and address may be updated for the next command without affecting an active flash command operation. 0: Cleared to 0 when read 1: Set to 1 when a write completes	0x0	RC
2	CMDDONE	This bit asserts when a command completes. If there are multiple commands, this status bit will assert after the first command completes and will stay asserted until read. 0: Cleared to 0 when read 1: Set to 1 when a command completes	0x0	RC
1	WRCLOSE	This bit is asserted when the user has written all key-hole registers for flash write and the controller has started the write. If this bit is high all key-hole registers (FEEFLADR, FEEFLDATA0, FEEFLDATA1) except the Command register (FEECMD) are closed for write.	0x0	R
0	CMDBUSY	Command busy. This bit is asserted when the flash block is executing any command entered via the command register.	0x0	R

Command Control Register: Interrupt Enable Register

Address: 0x40018004, Reset: 0x00000000, Name: FEECON0

Table 96. Bit Descriptions for FEECON0

Bits	Bit Name	Description	Reset	Access
[31:3]	RESERVED	Returns 0 when read.	0x0	R
2	IENERR	Command fail interrupt enable. If this bit is set then an interrupt will be generated when a command or flash write completes with an error status. 0: Disable 1: Enable	0x0	RW
1	IWRALCOMP	Write almost complete interrupt enable. Returns 0 when read. 0: Disable 1: Enable	0x0	RW
0	IENCMD	Command complete interrupt enable. When set, an interrupt will be generated when a command or flash write completes. 0: Disable 1: Enable	0x0	RW

Command Register

Address: 0x40018008, Reset: 0x00000000, Name: FEECMD

Table 97. Bit Descriptions for FEECMD

Bits	Bit Name	Description	Reset	Access
[31:5]	RESERVED	Returns 0x0. Always returns 0 when read.	0x0	RW
[4:0]	CMD	00000: IDLE. No command executed. 00001: PAGEERASE. Write the address of the page to be erased to the FEEADR0 register, then write this code to the FEECMD and the flash will erase the page. When the erase has completed the flash will read every location in the page to verify all words in the page are erased. If there is a read verify error this will be indicated in the Status register. To erase multiple pages wait until a previous page erase has completed – check the status then issue a command to start the next page erase. Before entering this command 0xF123F456 must be written to the FEEKEY register. 00010: SIGN. Use this command to generate a signature for a block of data. The signature is generated on a page by page basis. To generate a signature	0x0	RW

Bits	Bit Name	Description	Reset	Access
		<p>the address of the first page of the block is entered in the FEEADR0 register, the address of the last page is written to the FEEADR1 register, then write this code to the FEECMD register. When the command has completed the signature is available for reading in the Sign register. The last 4 bytes of the last page in a block is reserved for storing the signature. Before entering this command 0xF123F456 must be written to the FEEKEY register.</p> <p>00100: WRITE. Use this command to write to flash locations. This command needs a UserKey for writing into write protection location and userfaakey location. No key is required for other flash locations. This command takes the address, data from FEEADR, FEEFLDATA key-hole registers.</p> <p>00101: MASSERASE0. Erase all of Flash 0 user space. To enable this operation 0xF123F456 must be written to the FEEKEY register (this is to prevent accidental erases). When the mass erase has completed the controller will read every location to verify that all locations are 0xFFFFFFFFFFFFFFFF. If there is a read verify error this will be indicated in the Status register.</p> <p>00110: MASSERASE1. Erase all of Flash 1 user space. To enable this operation 0xF123F456 must be written to the FEEKEY register (this is to prevent accidental erases). When the mass erase has completed the controller will read every location to verify that all locations are 0xFFFFFFFFFFFFFFFF. If there is a read verify error this will be indicated in the Status register.</p> <p>01000: ABORT. If this command is issued then any command currently in progress will be stopped. The status will indicate command completed with an error status (FEESTA[5:4] = 0x3). Note that this is the only command that can be issued while another command is already in progress. This command can also be used to stop a write that may be in progress. If a write or erase is aborted then the flash timing will be violated and it is not possible to determine if the write or erase completed successfully. To enable this operation 0xF123F456 must be written to the FEEKEY register (this is to prevent accidental aborts).</p> <p>All other combinations: Reserved</p>		

Flash Address Keyhole Register

Address: 0x4001800C, Reset: 0x00000000, Name: FEEFLADR

Table 98. Bit Descriptions for FEEFLADR

Bits	Bit Name	Description	Reset	Access
[31:19]	RESERVED	Returns 0x0 if read.	0x0	R
[18:3]	FLADDR	Memory mapped address for the flash location. Used to specify flash address for write command. LSB 3 bits always reads zero.	0x0	RW
[2:0]	RESERVED	Returns 0x0 if read.	0x0	R

Flash Data Register: Keyhole Interface Lower 32 Bits

Address: 0x40018010, Reset: 0x00000000, Name: FEEFLDATA0

Table 99. Bit Descriptions for FEEFLDATA0

Bits	Bit Name	Description	Reset	Access
[31:0]	FLDATA0	FLDATA0 forms the lower 32 bit of 64 bit data to be written to flash.	0x0	RW

Flash Data Register: Key-Hole Interface Upper 32 Bits

Address: 0x40018014, Reset: 0x00000000, Name: FEEFLDATA1

Table 100. Bit Descriptions for FEEFLDATA1

Bits	Bit Name	Description	Reset	Access
[31:0]	FLDATA1	FLDATA1 forms the upper 32 bit of 64 bit data to be written to flash.	0x0	RW

Lower Page Address Register

Address: 0x40018018, Reset: 0x00000000, Name: FEEADR0

Table 101. Bit Descriptions for FEEADR0

Bits	Bit Name	Description	Reset	Access
[31:19]	RESERVED	Return 0 when read.	0x0	RW
[18:11]	PAGEADDR0	Used by SIGN and PAGEERASE commands for specifying page address. See the description of these commands in FEECMD.	0x0	RW
[10:0]	RESERVED	Reserved	0x0	R

Upper Page Address Register

Address: 0x4001801C, Reset: 0x00000000, Name: FEEADR1

Table 102. Bit Descriptions for FEEADR1

Bits	Bit Name	Description	Reset	Access
[31:19]	RESERVED	Return 0 when read.	0x0	RW
[18:11]	PAGEADDR1	Used by SIGN command for specifying the endpage address. See the description of this command in FEECMD.	0x0	RW
[10:0]	RESERVED	Reserved	0x0	R

Key Register

Address: 0x40018020, Reset: 0x00000000, Name: FEEKEY

Table 103. Bit Descriptions for FEEKEY

Bits	Bit Name	Description	Reset	Access
[31:0]	KEY	Enter 0xF123F456 to allow key protected operations. Returns 0x00 if read.	0x0	W

Write Protection Register for Flash 0

Address: 0x40018028, Reset: 0xFFFFFFFF, Name: FEEPRO0

Table 104. Bit Descriptions for FEEPRO0

Bits	Bit Name	Description	Reset	Access
[31:0]	WRPROTO	Write protection for Flash 0 – 32 bits. Each bit corresponds to a 4kB flash section. Writing 0 to a bit protects the corresponding section of flash. This register is read-only if the write protection in flash has been programmed.	0xFFFFFFFF	RW

Write Protection Register for Flash 1

Address: 0x4001802C, Reset: 0xFFFFFFFF, Name: FEEPRO1

Table 105. Bit Descriptions for FEEPRO1

Bits	Bit Name	Description	Reset	Access
[31:0]	WRPROT1	Write protection for Flash 1 – 32 bits. Each bit corresponds to a 4kB flash section. Writing 0 to a bit protects the corresponding section of flash. This register is read-only if the write protection in flash has been programmed.	0xFFFFFFFF	RW

Upper Halfword of Signature Register

Address: 0x40018034, Reset: 0x0000000X, Name: FEESIG

Table 106. Bit Descriptions for FEESIG

Bits	Bit Name	Description	Reset	Access
[31:24]	RESERVED	Returns 0x0 if read.	0x0	R
[23:0]	SIGN	24 bit signature.	0xx	R

User Setup Register

Address: 0x40018038, Reset: 0x0000001X, Name: FEECON1

This register is key-protected, so the key (0xF123F456) must be entered in FEEKEY. After writing to FEECON1, a value other than 0xF123F456 must be written again to FEEKEY, to re-assert the key protection.

Table 107. Bit Descriptions for FEECON1

Bits	Bit Name	Description	Reset	Access
[31:5]	RESERVED	Returns 0 when read.	0x0	R
4	MDIO	MDIO mode. This bit is for read-only purpose. If this bit is set then MDIO address swapping can be enabled.	0x1	R
3	SWAP	Swap program code for MDIO mode. 0: Disable Address swap for Userspace Flash 0 and Flash 1. 1: Enable Address swap for Userspace Flash 0 and Flash 1.	0xX	RW
2	INCR	Auto increment FEEFLAADR for non DMA operation. 0: Disable auto address increment 1: Enable auto address increment	0x0	RW
1	KHDMA	Key-hole DMA enable. 0: Disable DMA mode 1: Enable DMA mode	0x0	RW
0	DBG	JTAG debug enable. If this bit is '1' then access via the serial wire debug interface is enabled. If this bit is '0' then access via the serial wire debug interface is disabled. The kernel set this bit to '1' when it has finished executing, thus enabling debug access to a user. 0: Disable JTAG access 1: Enable JTAG access	0xX	RW

Write Abort Address Register

Address: 0x40018040, Reset: 0x0000000X, Name: FEEWRADDRA

Table 108. Bit Descriptions for FEEWRADDRA

Bits	Bit Name	Description	Reset	Access
[31:0]	WRABORTADDR	If a write is aborted then this register will contain the address of the location been written when the write was aborted. This register has appropriate value if command abort happened. This has to be read after the command is aborted. And this has to be read before any other command is given. After reset the value will be random.	0xx	R

Interrupt Abort Enable Register—Interrupt 31 to Interrupt 0

Address: 0x40018048, Reset: 0x00000000, Name: FEEAEN0

Table 109. Bit Descriptions for FEEAEN0

Bits	Bit Name	Description	Reset	Access
[31:0]	SYSIRQABORTEN	Lower 32 bits of system interrupt abort enable. To allow a system interrupt to abort a command (write, erase, sign or mass verify) then write a '1' to the appropriate bit in this register. Each bit corresponds to 1 interrupt listed in the interrupt vector table.	0x0	RW

Interrupt Abort Enable Register—Interrupt 54 to Interrupt 32

Address: 0x4001804C, Reset: 0x000000, Name: FEEAEN1

Table 110. Bit Descriptions for FEEAEN1

Bits	Bit Name	Description	Reset	Access
[22:0]	SYSIRQABORTEN	Upper 23 bits of system interrupt abort enable. To allow a system interrupt to abort a command (write, erase, sign or mass verify) then write a '1' to the appropriate bit in this register. Each bit corresponds to 1 interrupt listed in the interrupt vector table.	0x0	RW

Cache Status Register

Address: 0x400180C0, Reset: 0xX, Name: CACHESTAT

Cache Setup Register

Address: 0x400180C4, Reset: 0xX, Name: CACHESETUP

This register is key-protected, so the key (0xF123F456) must be entered in CACHEKEY

Cache Key Register

Address: 0x400180C8, Reset: 0xX, Name: CACHEKEY

SILICON IDENTIFICATION

The ADuCM320 has two silicon die, and each die has a register that identifies the silicon.

The CHIPID register contains the digital die silicon version in Bits[3:0] and the part identification in Bits[15:4].

The LVID register contains the low voltage die silicon version.

SILICON IDENTIFICATION MEMORY MAPPED REGISTERS

Table 111. Silicon ID Register Summary

Address	Name	Description	Reset	RW
0x40002024	CHIPID	Digital die ID	0x0561	R
0x40082C30	LVID	Low voltage die ID	0x0073	R

DIGITAL DIE ID REGISTER

Address: 0x40002024, Reset: 0x0561, Name: CHIPID

Table 112. Bit Descriptions for CHIPID

Bits	Bit Name	Description	Reset	Access
[15:4]	PARTID	Digital die part identifier.	0x56	R
[3:0]	REV	Digital die silicon revision number.	0x11	R

LOW VOLTAGE DIE ID REGISTER

Address: 0x40082C30, Reset: 0x0073, Name: LVID

Table 113. Bit Descriptions for LVID

Bits	Bit Name	Description	Reset	Access
[15:4]	LVID	Low voltage die part identifier.	0x7	R
[3:0]	LVREV	Low voltage die silicon revision number.	0x3 ¹	

¹ These values are based on initial released silicon. Previous/future revisions of silicon will have a different reset value.

DIGITAL I/Os

DIGITAL I/Os FEATURES

The ADuCM320 features multiple general-purpose bidirectional input/output (GPIO) pins. Most of the GPIO pins have multiple functions, configurable by user code. At power up, all but one of these pins are configured as GPIOs; one pin reflects the state of the POR. This pin can also be configured by user code to be used as a GPIO. On power-up, these pins are configured as inputs with their corresponding pull-up or pull-down disabled.

Shared MDIO Pins

The P3.0 to P3.6 port pins are disabled when they are enabled for MDIO (MDCON[1] = 0).

DIGITAL I/Os BLOCK DIAGRAM

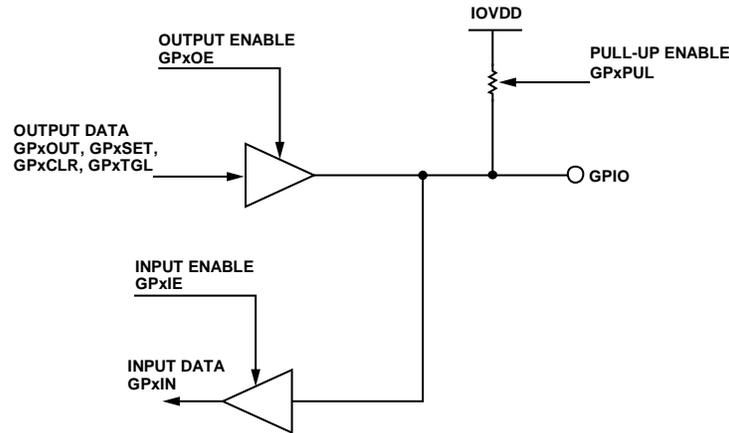

Figure 15. GPIO Structure for Port P0 to Port P3

The pin circuit of Port P0 to Port P3 is shown in Figure 15. Port P4 and Port P5 are essentially the same, but instead of the pull-ups, there are pull-downs to IOGND.

DIGITAL I/Os OVERVIEW

The GPIOs are grouped into six ports: Port 0 to Port 5. Each GPIO can be configured as input, output, or fully open circuit. The internal pull-up/pull-down can be enabled by software. All I/O pins are functional over the full supply range ($IOV_{DD} = 3.1\text{ V to }3.6\text{ V}$ (maximum)), and the logic input voltages are specified as percentages of the supply as follows:

$$V_{INL} = 0.2 \times IOV_{DD\ max}$$

$$V_{INH} = 0.7 \times IOV_{DD\ min}$$

The absolute maximum input voltage is $IOV_{DD} + 0.3\text{ V}$. The typical leakage current of the GPIOs configured as input or open circuit is 50 nA per GPIO. When the ADuCM320 enters a power saving mode, the GPIO pins retain their states. Note that in power save mode, a driving peripheral cannot drive the pin. That is, if the UART is driving the pin upon entry to deep sleep, it is isolated from the pin and power is gated. Its state and control are restored upon wake-up.

DIGITAL I/Os OPERATION

Each digital IO is configured, read, and written independent of the other bits.

GP Input Data (GPxIN)

GPxIN contains the pin input levels if enabled as inputs by GPxIE.

GP Output Data (GPxOUT)

The values of GPxOUT are output on the GPIO pins when configured as outputs by GPxOE.

I/O Data Out Enable (GPxOE)

GPxOE enables the values of GPxOUT to be output on the GPIO pins.

I/O Pull-Up Enable (GPxPUL)

GPxPUL enables/disables internal pull-ups/pull-downs. All Port 0 to Port 3 pins have internal pull-ups, and the Port 4 and Port 5 pins have pull-downs. The pull-ups/pull-downs are implemented as MOS devices, with typical performances shown in Figure 16 and Figure 17.

If a pin is configured as an open-drain output, it is not possible to enable the internal pull-up ; an external pull-up is required. This only affects open-drain output mode, not input mode.

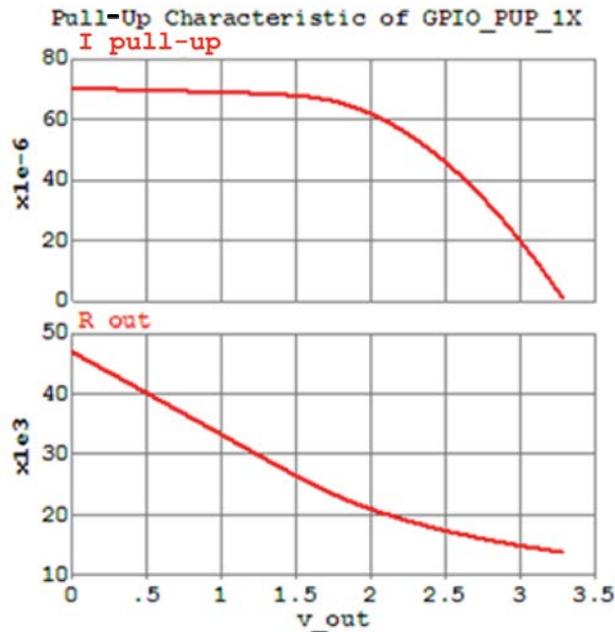

Figure 16. Typical P0 to P3 Pull-Up Characteristics

117B-116

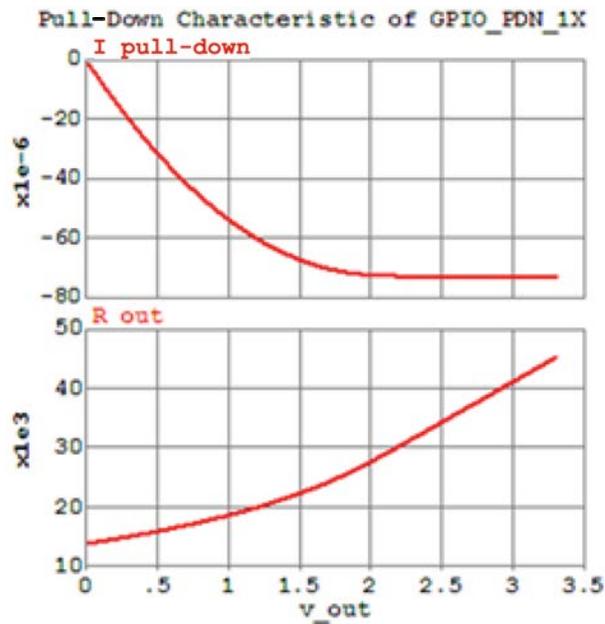

Figure 17. Typical P4 to P5 Pull-Down Characteristics

117B-117

I/O Data In Enable (GPxIE)

GPxIE enables the GPIO pin input levels to be available in GPxIN.

Open-Drain Enable (GPxODE)

GPxODE changes enabled outputs to open-drain mode. In this mode, the pin sinks current if the bit in GPxOUT.y is low. If the bit in GPxOUT.y is high, the pin does not source current, except via the internal pull-up if it is enabled. This is useful for wired AND and multidrop.

To enable a pin as an open-drain output, set the appropriate bits in GPxOEN and GPxODE.

If a pin is configured as an open-drain output, it is not possible to enable the internal pull-up ; an external pull-up is required. This only affects the open-drain output mode, not the input mode.

Bit Set

Bit set mode is used to set one or more GPIO data outputs without affecting other outputs within a port. Only the GPIO corresponding with the write data bit equal to 1 is set; the remaining GPIOs are unaffected.

Bit Clear

Bit clear mode is used to clear one or more GPIO data outputs without affecting other outputs within a port. Only the GPIO corresponding with the write data bit equal to 1 is cleared; the remaining GPIOs are unaffected.

Bit Toggle

Bit toggle mode is used to toggle one or more GPIO data outputs without affecting other outputs within a port. Only the GPIO corresponding to the write data bit equal to 1 is toggled; the remaining GPIOs are unaffected.

DIGITAL PORT MULTIPLEX

This block provides control over the GPIO functionality of specified pins because some of the pins offer the choice to work as a GPIO or to have other specific functions.

Table 114. GPIO Multiplex Table

GPIO	Configuration Modes

I²C SERIAL INTERFACE

I²C FEATURES

- Master or slave mode with 2-byte transmit and receive FIFOs
- Supports
 - 7-bit and 10-bit addressing modes
 - Four 7-bit device addresses or one 10-bit address and two 7-bit addresses in the slave
 - Repeated starts in master and slave modes
 - Clock stretching supported for the slave and master
 - Master arbitration
 - Continuous read mode for the master or up to 512 bytes fixed read
 - Internal and external loopback
- Support for DMA in master and slave modes
- Software control on the slave of NACK signal

I²C OVERVIEW

The I²C data transfer uses a serial clock pin (SCL) and a serial data pin (SDA). The pins are configured in a wired-AND'd format that allows arbitration in a multimaster system.

The transfer sequence of an I²C system consists of a master device initiating a transfer by generating a start condition while the bus is idle. The master transmits the slave device address and the direction of the data transfer during the initial address transfer. If the master does not lose arbitration and the slave acknowledges the initial address transfer, the data transfer is initiated. This continues until the master issues a stop condition and the bus becomes idle. Figure 5 shows a typical I²C transfer.

A master device can be configured to generate the serial clock. The frequency is programmed by the user in the serial clock divisor register, I2CxDIV (where x is 0 for I2C0 and 1 for I2C1). The master channel can be set to operate in fast mode (400 kHz) or standard mode (100 kHz).

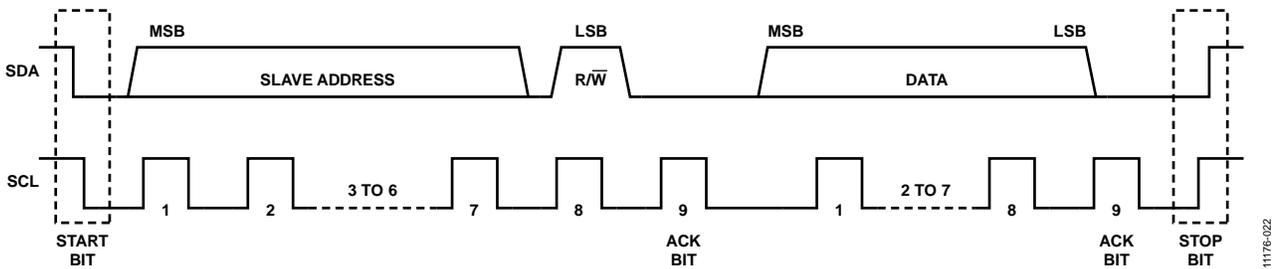

Figure 18. Typical I²C Transfer Sequence

The I²C bus peripheral address in the I²C bus system is programmed by the user. This ID can be modified any time a transfer is not in progress. The user can set up to four slave addresses that are recognized by the peripheral. The peripheral is implemented with a 2-byte FIFO for each transmit and receive shift register. The IRQ and status bits in the control registers are available to signal to the processor core when the FIFOs need to be serviced.

I²C OPERATION

I²C Startup

The following steps are required to run the I²C peripheral:

1. Configure the I²C clock in CLKCON1[10:8], CLKCON5[4] for I²C1, and CLKCON5[3] for I²C0.
2. Configure digital pins (P0.4/P0.5, P0.6/P0.7) for I²C operation via the GP0CON register.
3. Configure I²C registers as required for slave or master operation.
4. Enable the I²C slave or master interrupt source as required.

Note that the user should disable the internal pull-up resistors on the I²C pins via the GP0PUL register when using I²C.

Table 146. GPIO Multiplex

GPIO	Configuration Mode (01)
P0.4, P0.6	SCL
P0.5, P0.7	SDA

Addressing Modes

7-Bit Addressing

The I2CxID0, I2CxID1, I2CxID2, and I2CxID3 registers contain the slave device IDs. The device compares the four I2CxIDx registers to the address byte. To be correctly addressed, the seven MSBs of either ID register must be identical to that of the seven MSBs of the first received address byte. The LSB of the ID registers (the transfer direction bit) is ignored in the process of address recognition.

The master addresses a device using the I2CxADR0 register.

10-Bit Addressing

This feature is enabled by setting I2CxSCON[1] for master and slave mode.

The 10-bit address of the slave is stored in I2CxID0 and I2CxID1, where I2CxID0 contains the first byte of the address, and the R/W bit and the upper five bits must be programmed to 11110 as shown in Figure 19. I2CxID1 contains the remaining eight bits of the 10-bit address. I2CxID2 and I2CxID3 can still be programmed with 7-bit addresses.

The master communicates to a 10-bit address slave using the I2CxADR0 and I2CxADR1 registers. The format is described in Figure 19. To perform a read from a slave with a 10-bit address, the master must first send a 10-bit address with the read/write bit cleared, and then it must generate a repeated start and send only the first byte of the address with the read/write bit set. A repeated start is generated by writing to I2CxADR0 while the master is still busy.

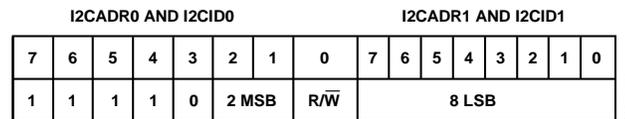

Figure 19. 10-Bit Address Format

A repeated start condition occurs when a second start condition is sent to a slave without a stop condition being sent in between. This allows the master to reverse the direction of the transfer by changing the R/W bit without having to give up control of the bus.

An example of a transfer sequence is shown in Figure 20. This sequence is generally used in cases where the first data sent to the part sets up the register address to be read from.

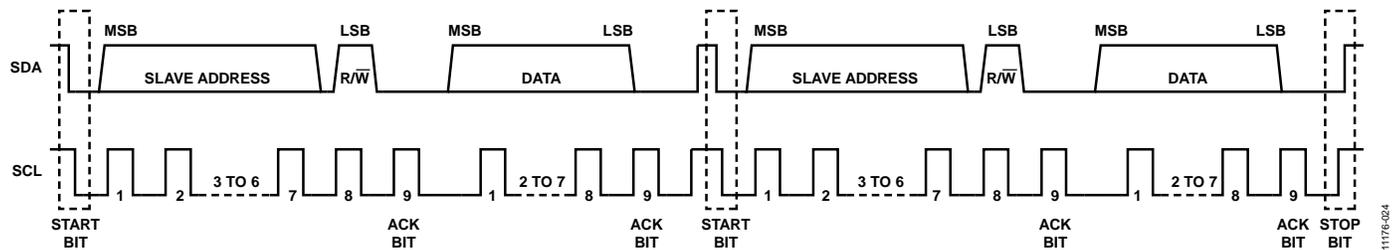

Figure 20. I²C Repeated Start Sequence

On the slave side, an interrupt is generated (if enabled in the I2CxSCON register) when a repeated start and a slave address are received. This can be differentiated from receiving a start and slave address by using the START and REPSTART status bits in the I2CxSSTA MMR.

On the master side, the master generates a repeated start if the I2CxADR0 register is written while the master is still busy with a transaction. After the state machine has started to transmit the device address, it is safe to write to the I2CxADR0 register.

For example, if a transaction involving a write, a repeated start, and then a read/write is required, write to the I2CxADR0 register either after the state machine starts to transmit the device address or after the first MTXREQ interrupt is received. When the transmit FIFO empties, a repeated start is generated.

Similarly, if a transaction involving a read, a repeated start, and then a read/write is required, write to the first master address byte register, I2CxADR1, either after the state machine starts to transmit the device address or after the first MRXREQ interrupt is received. When the requested receive count is reached, a repeated start is generated.

I²C Clock Control

The I²C peripherals are clocked by a gated 20 MHz system clock (PCLK). The CLKCON5[3] bit must be cleared to enable the clock to the I²C0 block. Similarly, the CLKCON5[4] bit must be cleared to enable the clock to the I²C1 block. The CLKCON1[10:8] bits allow the I²C block to be clocked with a slower clock by allowing the 20 MHz clock to be divided, which helps to reduce power.

The I²C master in the system generates the serial clock for a transfer. The master channel can be configured to operate in fast mode (400 kHz) or standard mode (100 kHz).

The bit rate is defined in the I2CxDIV MMR as follows:

$$f_{SCL} = f_{I2CCLK} / (LOW + HIGH + 3)$$

where:

$$f_{I2CCLK} = f_{PCLK} / I2CCD.$$

f_{PCLK} is the system clock, 20 MHz.

$I2CCD$ is the clock divide value and is set by the CLKCON1[10:8] bits.

$HIGH$ is the high period of the clock, $I2CxDIV[15:8] = (REQD_HIGH_TIME / UCLK_PERIOD) - 2$.

LOW is the low period of the clock, $I2CxDIV[7:0] = (REQD_LOW_TIME / UCLK_PERIOD) - 1$.

For 100 kHz SCL operation, with a low time of 5 μ s, a high time of 5 μ s, and a UCLK frequency of 20 MHz,

$$HIGH = (5 \mu s / (1 / 20,000,000)) - 2 = 98 = 0x62$$

$$LOW = (5 \mu s / (1 / 20,000,000)) - 1 = 99 = 0x63$$

$$f_{SCL} = 20,000,000 / (98 + 99 + 3) = 100 \text{ kHz}$$

Resetting the I²C block

Three steps are needed to reset the I²C block.

In master mode,

1. Clear I2CxMCON[0] to 0. This disables the I²C master.
2. Set I2CxSHCON[0] to 1. This is a write only register. Writing to this bit resets the start/stop detection circuits of the I²C block and clears the LINEBUSY status bit (I2CxMSTA[10]).
3. Set I2CxMCON[0]= 1 to reenable the I²C master.

In slave mode,

1. Clear I2CxSCON[0] to 0. This disables the I²C slave.
2. Set I2CxSHCON[0] to 1. This is a write only register. Writing to this bit resets the start/stop detection circuits of the I²C block.
3. Set I2CxSCON[0] to 1 to reenable the I²C slave

Do not reset the I²C peripheral on two consecutive communication sequences.

I²C OPERATING MODES

Master Transfer Initiation

If the master enable bit (I2CxMCON[0], MASEN) is set, a master transfer sequence is initiated by writing a value to the I2CxADR_x register. If there is valid data in the I2CxMTX register, it is the first byte transferred in the sequence after the address byte during a write sequence.

Slave Transfer Initiation

If the slave enable bit (I2CxSCON[0], SLVEN) is set, a slave transfer sequence is monitored for the device address in Register I2CxID0, Register I2CxID1, Register I2CxID2, or Register I2CxID3. If the device address is recognized, the part participates in the slave transfer sequence.

Note that a slave operation always starts with the assertion of one of three interrupt sources—read request (MRXREQ/ SRXREQ), write request (MTXREQ, STXREQ), or general call (GCINT) interrupt—and the software should always look for a stop interrupt to ensure that the transaction has completed correctly and to deassert the stop interrupt status bit.

Rx/Tx Data FIFOs

The transmit datapath consists of a master and slave Tx FIFO, I2CxMTX and I2CxSTX, that are each two bytes deep and a transmit shifter. The transmit status bits in I2CxMSTA[1:0] and I2CxSSTA[0] denote whether there is valid data in the Tx FIFO. Data from the Tx FIFO is loaded into the Tx shifter when a serial byte begins transmission. If the Tx FIFO is not full during an active transfer sequence, the transmit request bit (I2CxMSTA[2] or I2CxSSTA[2]) asserts.

In the slave, if there is no valid data to transmit when the Tx shifter is loaded, the transmit underflow status bit asserts (I2CxMSTA[12], I2CxSSTA[1]).

The master generates a stop condition if there is no data in the transmit FIFO and the master is writing data.

The receive datapath consists of a master and slave Rx FIFO, I2CxMRX and I2CxSRX, that are each two bytes deep. The receive request interrupt bit (I2CxMSTA[3] or I2CxSSTA[3]) indicates whether there is valid data in the Rx FIFO. Data is loaded into the Rx FIFO after each byte is received. If valid data in the Rx FIFO is overwritten by the Rx shifter, the receive overflow status bit (I2CxMSTA[9] or I2CxSSTA[4]) is asserted.

Master NACK

When receiving data, the master responds with a NACK if its FIFO is full and an attempt is made to write another byte to the FIFO. This last byte received is not written to the FIFO and is lost.

No Acknowledge from the Slave

If the slave does not want to acknowledge a read access, then simply not writing data into the slave transmit FIFO results in a NACK.

If the slave does not want to acknowledge a master write, assert the NACK bit in the slave control register, I2CxSCON[7].

Normally, the slave acknowledges all bytes written into the receive FIFO. If the receive FIFO fills up, the slave cannot write further bytes to it, and it does not acknowledge subsequent bytes not written to the FIFO. The master should then stop the transaction.

The slave does not acknowledge a matching device address if the read/write bit is set and the transmit FIFO is empty. Therefore, there is very little time for the microcontroller to respond to a slave transmit request and the assertion of ACK. It is recommended that EARLYTXR (I2CxSCON[5]) be asserted for this reason.

General Call

An I²C general call is for addressing every device on the I²C bus. A general call address is 0x00 or 0x01. The first byte, address byte is followed by a command byte.

If the address byte is 0x00, then Byte 2, the command byte, can be one of the following:

- 0x6: the I²C interface (master and slave) is reset. The general call interrupt status asserts, and the general call ID bits, GCID (I2CxSSTA[9:8]), are 0x1. User code should take corrective action to reset the entire system or simply reenable the I²C interface.
- 0x4: the general call interrupt status bit is asserted, and the general call ID bits (GCID) are 0x2.

If the address byte is 0x01, a hardware general call is issued.

- Byte 2 in this case is the hardware master address.

The general call interrupt status bit is set on any general call after the second byte is received, and user code should take corrective action to reprogram the device address.

If GCEN is asserted, the slave always acknowledges the first byte of a general call. It acknowledges the second byte of a general call if the second byte is 0x04 or 0x06 or if the second byte is a hardware general call and HGCEN (I2CxSCON[3]) is asserted.

The I2CxALT register contains the alternate device ID for a hardware general call sequence. If the hardware general call enable bit (HGCEN), the general call enable bit (GCEN), and the slave enable bit (SLVEN) are all set, the device recognizes a hardware general call. When a general call sequence is issued and the second byte of the sequence is identical to ALT, the hardware call sequence is recognized for the device.

I²C Reset Mode

The slave state machine is reset when SLVEN is written to 0.

The master state machine is reset when MASEN is written to 0.

I²C Test Modes

The device can be placed in an internal loopback mode by setting the LOOPBACK bit (I2CxMCON[2]). There are four FIFOs (master Tx and Rx, and slave Tx and Rx); therefore the I²C peripheral can, in effect, be set up to talk to itself. External loopback can be performed if the master is set up to address the slave address.

I²C Low Power Mode

If the master and slave are both disabled (MASEN = SLVEN = 0), the I²C section is off. To fully power down the I²C block, the clock to the I²C section of the chip should be disabled by setting CLKCON5[4:3] = 0x3

DMA Requests

Four DMA channels are required to service the I²C master and slave. DMA enable bits are provided in the slave control register and in the master control register.

7	IENACK	ACK not received interrupt enable. 0: ACK not received interrupt disable 1: ACK not received interrupt enable	0x0	RW
6	IENALOST	Arbitration lost interrupt enable. 0: Arbitration lost interrupt disable 1: Arbitration lost interrupt enable	0x0	RW
5	IENMTX	Transmit request interrupt enable. 0: Transmit request interrupt disable 1: Transmit request interrupt enable	0x0	RW

Bits	Bit Name	Description	Reset	Access
4	IENMRX	Receive request interrupt enable. 0: Receive request interrupt disable 1: Receive request interrupt enable	0x0	RW
3	STRETCH	Stretch SCL enable. 0: Disable Clock stretching 1: Setting this bit tells the device if SCL is 0 hold it at 0; Or if SCL is 1 then when it next goes to 0 hold it at 0.	0x0	RW
2	LOOPBACK	Internal loopback enable. Note that is also possible for the master to loop back a transfer to the slave as long as the device address corresponds, i.e. external loopback. 0: SCL and SDA out of the device are not muxed onto their corresponding inputs. 1: SCL and SDA out of the device are muxed onto their corresponding inputs.	0x0	RW
1	COMPETE	Start back-off disable. Setting this bit enables the device to compete for ownership even if another device is currently driving a START condition.	0x0	RW
0	MASEN	Master enable. The master should be disabled when not in use as this will gate the clock to the master and save power. This bit should not be cleared until a transaction has completed, see the TCOMP bit in the master status register. 0: Master is disabled 1: Master is enabled	0x0	RW

Master Status Register

Address: 0x40003004, Reset: 0x6000, Name: I2C0MSTA

Table 149. Bit Descriptions for I2C0MSTA

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	SCL_FILTERED	State of SCL Line. This bit is the output of the glitch-filter on SCL. SCL is always pulled high when undriven.	0x1	R
13	SDA_FILTERED	State of SDA Line. This bit is the output of the glitch-filter on SDA. SDA is always pulled high when undriven.	0x1	R
12	MTXUFLOW	Master Transmit Underflow. Asserts when the I2C0 master ends the transaction due to Tx-FIFO empty condition. This bit is asserted only when the IENMTX bit is set.	0x0	RC
11	MSTOP	STOP driven by this I2C0 Master. Asserts when this I2C0 master drives a STOP condition on the I2C0 bus. This bit, when asserted, can indicate a Transaction completion, Tx-underflow, Rx-overflow or a NACK by the slave. This is different from the TCOMP as this bit is not asserted when the STOP condition occurs due to any other I2C0 master. No interrupt is generated for the assertion of this bit. However, if IENCOMP is 1, every STOP condition will generate an interrupt and this bit can be read. When this bit is read, it will clear status.	0x0	RC
10	LINEBUSY	Line is busy. Asserts when a START is detected on the I2C0 bus. De-asserts when a STOP is detected on the I2C0 bus.	0x0	R
9	MRXOF	Master Receive FIFO overflow. Asserts when a byte is written to the receive FIFO when the FIFO is already full. When the bit is read it will clear status.	0x0	RC
8	TCOMP	Transaction complete or stop detected. Transaction complete. This bit will assert when a STOP condition is detected on the I2C0 bus. If IENCOMP is 1, an interrupt will be generated when this bit asserts. This bit will only assert if the master is enabled (MASEN = 1). This bit should be used to determine when it is safe to disable the master. It can also be used to wait for another master transaction to complete on the I2C0 bus when this master loses arbitration. When this bit is read it will clear status. This bit can drive an interrupt.	0x0	RC

Bits	Bit Name	Description	Reset	Access
7	NACKDATA	ACK not received in response to data write. This bit will assert when an ACK is not received in response to a data write transfer. If IENACK is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt. This bit is cleared on a read of the I2COMSTA register.	0x0	RC
6	MBUSY	Master busy. This bit indicates that the master state machine is servicing a transaction. It will be clear if the state machine is idle or another device has control of the I2C0 bus.	0x0	R
5	ALOST	Arbitration lost. This bit will assert if the master loses arbitration. If IENALOST is 1, an interrupt will be generated when this bit asserts. This bit is cleared on a read of the I2COMSTA register. This bit can drive an interrupt.	0x0	RC
4	NACKADDR	ACK not received in response to an address. This bit will assert if an ACK is not received in response to an address. If IENACK is 1, an interrupt will be generated when this bit asserts. This bit is cleared on a read of the I2COMSTA register. This bit can drive an interrupt.	0x0	RC
3	MRXREQ	Master Receive request. This bit will assert when there is data in the receive FIFO. If IENMRX is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt.	0x0	R
2	MTXREQ	Master Transmit request. This bit will assert when the direction bit is 0 and the transmit FIFO is either empty or not full. If IENMTX is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt.	0x0	R
[1:0]	MTXFSTA	Master Transmit FIFO status. These 2 bits show the master transmit FIFO status and can be decoded as follows: 00 = FIFO Empty 10 = 1 byte in FIFO 11 = FIFO Full.	0x0	R

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	ICMRX	Master receive register. This register allows access to the receive data FIFO. The FIFO can hold 2 bytes.	0x0	R

Master Transmit Data Register

Address: 0x4000300C, Reset: 0x0000, Name: I2COMTX

Table 151. Bit Descriptions for I2COMTX

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	I2COMTX	Master transmit register. For test and debug purposes, when read, this register returns the byte that is currently being transmitted by the master. That is a byte written to the transmit register can be read back some time later when that byte is being transmitted on the line. This register allows access to the transmit data FIFO. The FIFO can hold 2 bytes.	0x0	RW

Master Receive Data Count Register

Address: 0x40003010, Reset: 0x0000, Name: I2COMRXCNT

Table 152. Bit Descriptions for I2COMRXCNT

Bits	Bit Name	Description	Reset	Access
[15:9]	RESERVED		0x0	R
8	EXTEND	Extended read. Use this bit if greater than 256 bytes are required on a read. For example, to receive 412 bytes write 0x100 (EXTEND = 1) to the I2COMRXCNT register. Wait for the first byte to be received, then check the I2COMRXCNT register for every byte received thereafter. When COUNT returns to 0, 256 bytes have been received. Then write 0x09C to the I2COMRXCNT register.	0x0	RW
[7:0]	COUNT	Receive count. Program the number of bytes required minus one to this register. If just 1 byte is required write 0 to this register. If greater than 256 bytes are required then use EXTEND.	0x0	RW

Master Current Receive Data Count Register

Address: 0x40003014, Reset: 0x0000, Name: I2COMCRXCNT

Table 153. Bit Descriptions for I2COMCRXCNT

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	COUNT	Current receive count. This register gives the total number of bytes received so far. If 256 bytes are requested then this register will read 0 when the transaction has completed.	0x0	R

First Master Address Byte Register

Address: 0x40003018, Reset: 0x0000, Name: I2C0ADR0

Table 154. Bit Descriptions for I2C0ADR0

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	ADR0	Address byte 0. If a 7 bit address is required, Bit 7 to Bit 1 of ADR0 are programmed with the address and Bit 0 of ADR0 is programmed with the direction (0 = Write, 1 = Read) If a 10 bit address is required, Bit 7 to Bit 3 of ADR0 are programmed with 11110, Bit 2 to Bit 1 of ADR0 are programmed with the 2 MSBs of the address and Bit 0 of ADR0 is programmed to 0.	0x0	RW

Second Master Address Byte Register

Address: 0x4000301C, Reset: 0x0000, Name: I2C0ADR1

Table 155. Bit Descriptions for I2C0ADR1

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	ADR1	Address byte 1. This register is only required when addressing a slave with a 10 bit address. Bit 7 to Bit 0 of ADR1 are programmed with the lower 8 bits of the address.	0x0	RW

Serial Clock Period Divisor Register

Address: 0x40003024, Reset: 0x1F1F, Name: I2C0DIV

Table 156. Bit Descriptions for I2C0DIV

Bits	Bit Name	Description	Reset	Access
[15:8]	HIGH	Serial clock high time. This register controls the clock high time. The timer is driven by the core clock (UCLK). Use the following equation to derive the required high time. $HIGH = (REQD_HIGH_TIME/UCLK_PERIOD) - 2$ For example to generate a 400kHz SCL with a low time of 1300ns and a high time of 1200ns, with a core clock frequency of 50MHz: $LOWTIME = 1300ns/20ns - 1 = 0x40$ (64 decimal) $HIGH = 1200ns/20ns - 2 = 0x3A$ (58 decimal). This register is reset to 0x1F which gives an SCL high time of 33 UCLK ticks. tHD:STA is also determined by the HIGH. $tHD:STA = (HIGH-1) \times uclk_period$. As tHD:STA must be 600ns; with UCLK = 50MHz the minimum value for HIGH is 31. This gives an SCL high time of 660ns.	0x1F	RW
[7:0]	LOW	Serial clock low time. This register controls the clock low time. The timer is driven by the core clock (UCLK). Use the following equation to derive the required low time. $LOW = (REQD_LOW_TIME/UCLK_PERIOD) - 1$ This register is reset to 0x1F which gives an SCL low time of 32 UCLK ticks.	0x1F	RW

Slave Control Register

Address: 0x40003028, Reset: 0x0000, Name: I2C0SCON

Table 157. Bit Descriptions for I2C0SCON

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	STXDMA	Enable slave Tx DMA request. Set to 1 by user code to enable I2C0 slave DMA Rx requests. Cleared by user code to disable DMA mode.	0x0	RW
13	SRXDMA	Enable slave Rx DMA request. Set to 1 by user code to enable I2C0 slave DMA Rx requests. Cleared by user code to disable DMA mode.	0x0	RW
12	IENREPST	Repeated start interrupt enable. If 1 an interrupt will be generated when the REPSTART status bit asserts. If 0 an interrupt will not be generated when the REPSTART status bit asserts.	0x0	RW
11	RESERVED	Reserved.	0x0	RW
10	IENSTX	Slave Transmit request interrupt enable.	0x0	RW
9	IENSRX	Slave Receive request interrupt enable.	0x0	RW
8	IENSTOP	Stop condition detected interrupt enable.	0x0	RW
7	NACK	NACK next communication. If this bit is set the next communication will be NACK 'ed. This could be used for example if during a 24xx style access, an attempt was made to write to a 'read only' or nonexisting location in system memory. That is the indirect address in a 24xx style write pointed to an unwritable memory location.	0x0	RW
6	STRETCHSCL	Stretch SCL enable. Setting this bit tells the device if SCL is '0' hold it at '0', or if SCL is '1' then when it next goes to '0' hold it at '0'.	0x0	RW
5	EARLYTXR	Early transmit request mode. Setting this bit enables a transmit request just after the positive edge of the direction bit SCL clock pulse.	0x0	RW
4	GCSBCLR	General call status bit clear. The General Call status and General Call ID bits are cleared when a '1' is written to this bit. The General Call status and General Call ID bits are not reset by anything other than a write to this bit or a full reset.	0x0	W

Bits	Bit Name	Description	Reset	Access
3	HGCEN	Hardware general call enable. When this bit and the General Call enable bit are set the device after receiving a general call, address 00h and a data byte checks the contents of the ALT against the receive shift register. If they match the device has received a 'hardware general call'. This is used if a device needs urgent attention from a master device without knowing which master it needs to turn to, it can use this call. This is a call "to whom it may concern". The device that requires attention embeds its own address into the message. The LSB of the ALT register should always be written to a 1, as per I2C0 January 2000 specification.	0x0	RW
2	GCEN	General call enable. This bit enables the I2C0 slave to ACK an I2C0 general call, address 0x00 (Write).	0x0	RW
1	ADR10EN	Enabled 10-bit addressing. If this bit is clear, the slave can support four slave addresses, programmed in Register I2C0ID0 to Register I2C0ID3. When this bit is set, 10 bit addressing is enabled. One 10 bit address is supported by the slave and is stored in I2C0ID0 and I2C0ID1, where I2C0ID0 contains the first byte of the address and the upper 5 bits must be programmed to 11110. I2C0ID3 and I2C0ID4 can be programmed with 7 bit addresses at the same time.	0x0	RW
0	SLVEN	Slave enable. When '1' the slave is enabled. When '0' all slave state machine flops are held in reset and the slave is disabled.	0x0	RW

Slave I2C0 Status/Error/IRQ Register

Address: 0x4000302C, Reset: 0x0001, Name: I2C0SSTA

Table 158. Bit Descriptions for I2C0SSTA

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	START	Start and matching address. This bit is asserted if a start is detected on SCL/SDA and the device address matched, or a general call(GC - 0000_0000) code is received and GC is enabled, or a High Speed (HS - 0000_1XXX) code is received, or a start byte (0000_0001) is received. It is cleared on receipt of either a stop or start condition.	0x0	R
13	REPSTART	Repeated start and matching address. This bit is asserted if START is already asserted and then a repeated start is detected. It is cleared when read or on receipt of a STOP condition. This bit can drive an interrupt.	0x0	RC
[12:11]	IDMAT	Device ID matched. 00: Received address matched ID register 0 01: Received address matched ID register 1 10: Received address matched ID register 2 11: Received address matched ID register 3	0x0	R
10	STOP	Stop after start and matching address. Gets set by hardware if the slave device received a STOP condition after a previous START condition and a matching address. Cleared by a read of the status register. If STOPINTEN in the slave control register is asserted, then the slave interrupt request will assert when this bit is set. This bit can drive an interrupt.	0x0	RC
[9:8]	GCID	General ID. GCID is cleared when the GCSBCLR is written to 1. These status bits will not be cleared by a 'General call reset'. 00: No general call 01: General call reset and program address 10: General call program address 11: General call matching alternative ID	0x0	R
7	GCINT	General call interrupt. This bit always drives an interrupt. The bit is asserted if the slave device receives a general call of any type. To clear, write 1 to the GCSBCLR in the slave control register. If it was a general call reset, all registers will be at their default values. If it was a hardware general call, the Rx FIFO holds the second byte of the general call, and this can be compared with the ALT register.	0x0	R

Bits	Bit Name	Description	Reset	Access
6	SBUSY	Slave busy. Set by hardware if the slave device receives a I2C0 START condition. Cleared by hardware when the address does not match an ID register, the slave device receives a I2C0 STOP condition, or if a repeated start address does not match.	0x0	R
5	NOACK	Ack not generated by the slave. When asserted, it indicates that the slave responded to its device address with a NOACK. It is asserted if there was no data to transmit and sequence was a slave read or if the NACK bit was set in the slave control register and the device was addressed. This bit is cleared on a read of the I2C0SSTA register.	0x0	RC
4	SRXOF	Slave Receive FIFO overflow. Asserts when a byte is written to the slave receive FIFO when the FIFO is already full.	0x0	RC
3	SRXREQ	Slave Receive request. SRXREQ asserts whenever the slave receive FIFO is not empty. Read or flush the slave receive FIFO to clear this bit. This bit will assert on the falling edge of the SCL clock pulse that clocks in the last data bit of a byte. This bit can drive an interrupt.	0x0	RC
2	STXREQ	Slave Transmit request. If EARLYTXR = 0, STXREQ is set when the direction bit for a transfer is received high. There after, as long as the transmit FIFO is not full this bit will remain asserted. Initially, it is asserted on the negative edge of the SCL pulse that clocks in the direction bit (if the device address matched also). If EARLYTXR = 1, STXREQ is set when the direction bit for a transfer is received high. There after, as long as the transmit FIFO is not full this bit will remain asserted. Initially, it is asserted after the positive edge of the SCL pulse that clocks in the direction bit (if the device address matched also). This bit is cleared on a read of the I2C0SSTA register.	0x0	RC
1	STXUR	Slave Transmit FIFO underflow. Is set if a master requests data from the device, and the Tx FIFO is empty for the rising edge of SCL.	0x0	RC
0	STXFSEREQ	Slave Tx FIFO Status or early request. If EARLYTXR = 0, this bit is asserted whenever the slave Tx FIFO is empty. If EARLYTXR = 1, TXFSEREQ is set when the direction bit for a transfer is received high. It asserts on the positive edge of the SCL clock pulse that clocks in the direction bit (if the device address matched also). It only asserts once for a transfer. It is cleared when read if EARLYTXR is asserted.	0x1	RW

Slave Receive Register

Address: 0x40003030, Reset: 0x0000, Name: I2C0SRX

REGISTER DETAILS: I2C1**Master Control Register**

Address: 0x40003400, Reset: 0x0000, Name: I2C1MCON

Table 169. Bit Descriptions for I2C1MCON

Bits	Bit Name	Description	Reset	Access
[15:12]	RESERVED		0x0	R
11	MTXDMA	Enable master Tx DMA request. 0: Disable DMA mode 1: Enable I2C master DMA Tx requests.	0x0	W
10	MRXDMA	Enable master Rx DMA request. 0: Disable DMA mode 1: Enable I2C master DMA Rx requests.	0x0	W
9	RESERVED		0x0	RW
8	IENCOMP	Transaction completed (or stop detected) interrupt enable. 0: An interrupt is not generated when a STOP is detected. 1: An interrupt is generated when a STOP is detected.	0x0	RW
7	IENACK	ACK not received interrupt enable. 0: ACK not received interrupt disable 1: ACK not received interrupt enable	0x0	RW
6	IENALOST	Arbitration lost interrupt enable. 0: Arbitration lost interrupt disable 1: Arbitration lost interrupt enable	0x0	RW
5	IENMTX	Transmit request interrupt enable. 0: Transmit request interrupt disable 1: Transmit request interrupt enable	0x0	RW

Bits	Bit Name	Description	Reset	Access
4	IENMRX	Receive request interrupt enable. 0: Receive request interrupt disable 1: Receive request interrupt enable	0x0	RW
3	STRETCH	Stretch SCL enable. 0: Disable Clock stretching 1: Setting this bit tells the device if SCL is 0 hold it at 0; Or if SCL is 1 then when it next goes to 0 hold it at 0.	0x0	RW
2	LOOPBACK	Internal loopback enable. Note that is also possible for the master to loop back a transfer to the slave as long as the device address corresponds, i.e. external loopback. 0: SCL and SDA out of the device are not muxed onto their corresponding inputs. 1: SCL and SDA out of the device are muxed onto their corresponding inputs.	0x0	RW
1	COMPETE	Start back-off disable. Setting this bit enables the device to compete for ownership even if another device is currently driving a START condition.	0x0	RW
0	MASEN	Master enable. The master should be disabled when not in use as this will gate the clock to the master and save power. This bit should not be cleared until a transaction has completed, see the TCOMP bit in the master status register. 0: Master is disabled 1: Master is enabled	0x0	RW

Master Status Register

Address: 0x40003404, Reset: 0x6000, Name: I2C1MSTA

Table 170. Bit Descriptions for I2C1MSTA

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	SCL_FILTERED	State of SCL Line. This bit is the output of the glitch-filter on SCL. SCL is always pulled high when undriven.	0x1	R
13	SDA_FILTERED	State of SDA Line. This bit is the output of the glitch-filter on SDA. SDA is always pulled high when undriven.	0x1	R
12	MTXUFLOW	Master Transmit Underflow. Asserts when the I2C master ends the transaction due to Tx-FIFO empty condition. This bit is asserted only when the IENMTX bit is set.	0x0	RC
11	MSTOP	STOP driven by this I2C Master. Asserts when this I2C master drives a STOP condition on the I2C bus. This bit, when asserted, can indicate a Transaction completion, Tx-underflow, Rx-overflow or a NACK by the slave. This is different from the TCOMP as this bit is not asserted when the STOP condition occurs due to any other I2C master. No interrupt is generated for the assertion of this bit. However, if IENCMP is 1, every STOP condition will generate an interrupt and this bit can be read. When this bit is read, it will clear status.	0x0	RC
10	LINEBUSY	Line is busy. Asserts when a START is detected on the I2C bus. De-asserts when a STOP is detected on the I2C bus.	0x0	R
9	MRXOF	Master Receive FIFO overflow. Asserts when a byte is written to the receive FIFO when the FIFO is already full. When the bit is read it will clear status.	0x0	RC
8	TCOMP	Transaction complete or stop detected. Transaction complete. This bit will assert when a STOP condition is detected on the I2C bus. If IENCMP is 1, an interrupt will be generated when this bit asserts. This bit will only assert if the master is enabled (MASEN = 1). This bit should be used to determine when it is safe to disable the master. It can also be used to wait for another master transaction to complete on the I2C bus when this master loses arbitration. When this bit is read it will clear status. This bit can drive an interrupt.	0x0	RC

Bits	Bit Name	Description	Reset	Access
7	NACKDATA	ACK not received in response to data write. This bit will assert when an ACK is not received in response to a data write transfer. If IENACK is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt. This bit is cleared on a read of the I2C1MSTA register.	0x0	RC
6	MBUSY	Master busy. This bit indicates that the master state machine is servicing a transaction. It will be clear if the state machine is idle or another device has control of the I2C bus.	0x0	R
5	ALOST	Arbitration lost. This bit will assert if the master loses arbitration. If IENALOST is 1, an interrupt will be generated when this bit asserts. This bit is cleared on a read of the I2C1MSTA register. This bit can drive an interrupt.	0x0	RC
4	NACKADDR	ACK not received in response to an address. This bit will assert if an ACK is not received in response to an address. If IENACK is 1, an interrupt will be generated when this bit asserts. This bit is cleared on a read of the I2C1MSTA register. This bit can drive an interrupt.	0x0	RC
3	MRXREQ	Master Receive request. This bit will assert when there is data in the receive FIFO. If IENMRX is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt.	0x0	R
2	MTXREQ	Master Transmit request. This bit will assert when the direction bit is 0 and the transmit FIFO is either empty or not full. If IENMTX is 1, an interrupt will be generated when this bit asserts. This bit can drive an interrupt.	0x0	R
[1:0]	MTXFSTA	Master Transmit FIFO status. These 2 bits show the master transmit FIFO status and can be decoded as follows: 00 = FIFO Empty 10 = 1 byte in FIFO 11 = FIFO Full.	0x0	R

Master Receive Data Register

Address: 0x40003408, Reset: 0x0000, Name: I2C1MRX

[15:8]	RESERVED		0x0	R
[7:0]	I2CMTX	Master transmit register. For test and debug purposes, when read, this register returns the byte that is currently being transmitted by the master. That is a byte written to the transmit register can be read back some time later when that byte is being transmitted on the line. This register allows access to the transmit data FIFO. The FIFO can hold 2 bytes.	0x0	RW

Master Receive Data Count Register

Address: 0x40003410, Reset: 0x0000, Name: I2C1MRXCNT

Table 173. Bit Descriptions for I2C1MRXCNT

Bits	Bit Name	Description	Reset	Access
[15:9]	RESERVED		0x0	R
8	EXTEND	Extended read. Use this bit if greater than 256 bytes are required on a read. For example, to receive 412 bytes write 0x100 (EXTEND = 1) to the I2CMRXCNT register. Wait for the first byte to be received, then check the I2CMCRXCNT register for every byte received thereafter. When COUNT returns to 0, 256 bytes have been received. Then write 0x09C to the I2CMRXCNT register.	0x0	RW
[7:0]	COUNT	Receive count. Program the number of bytes required minus one to this register. If just 1 byte is required write 0 to this register. If greater than 256 bytes are required then use EXTEND.	0x0	RW

Master Current Receive Data Count Register

Address: 0x40003414, Reset: 0x0000, Name: I2C1MCRXCNT

Table 174. Bit Descriptions for I2C1MCRXCNT

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	COUNT	Current receive count. This register gives the total number of bytes received so far. If 256 bytes are requested then this register will read 0 when the transaction has completed.	0x0	R

First Master Address Byte Register

Address: 0x40003418, Reset: 0x0000, Name: I2C1ADR0

Table 175. Bit Descriptions for I2C1ADR0

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	ADR0	Address byte 0. If a 7 bit address is required, Bit 7 to Bit 1 of ADR0 are programmed with the address and Bit 0 of ADR0 is programmed with the direction (0 = Write, 1 = Read) If a 10 bit address is required, Bit 7 to Bit 3 of ADR0 are programmed with 11110, Bit 2 to Bit 1 of ADR0 are programmed with the 2 MSBs of the address and Bit 0 of ADR0 is programmed to 0.	0x0	RW

Second Master Address Byte Register

Address: 0x4000341C, Reset: 0x0000, Name: I2C1ADR1

Table 176. Bit Descriptions for I2C1ADR1

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	ADR1	Address byte 1. This register is only required when addressing a slave with a 10 bit address. Bit 7 to Bit 0 of ADR1 are programmed with the lower 8 bits of the address.	0x0	RW

Serial Clock Period Divisor Register

Address: 0x40003424, Reset: 0x1F1F, Name: I2C1DIV

Table 177. Bit Descriptions for I2C1DIV

Bits	Bit Name	Description	Reset	Access
[15:8]	HIGH	Serial clock high time. This register controls the clock high time. The timer is driven by the core clock (UCLK). Use the following equation to derive the required high time. $\text{HIGH} = (\text{REQD_HIGH_TIME}/\text{UCLK_PERIOD}) - 2$ For example to generate a 400kHz SCL with a low time of 1300ns and a high time of 1200ns, with a core clock frequency of 50MHz: $\text{LOWTIME} = 1300\text{ns}/20\text{ns} - 1 = 0x40 \text{ (64 decimal)}$ $\text{HIGH} = 1200\text{ns}/20\text{ns} - 2 = 0x3A \text{ (58 decimal)}$ This register is reset to 0x1F which gives an SCL high time of 33 UCLK ticks. tHD:STA is also determined by the HIGH. $\text{tHD:STA} = (\text{HIGH}-1) \times \text{uclk_period}$ As tHD:STA must be 600ns; with UCLK = 50MHz the minimum value for HIGH is 31. This gives an SCL high time of 660ns.	0x1F	RW
[7:0]	LOW	Serial clock low time. This register controls the clock low time. The timer is driven by the core clock (UCLK). Use the following equation to derive the required low time. $\text{LOW} = (\text{REQD_LOW_TIME}/\text{UCLK_PERIOD}) - 1$ This register is reset to 0x1F which gives an SCL low time of 32 UCLK ticks.	0x1F	RW

Slave Control Register

Address: 0x40003428, Reset: 0x0000, Name: I2C1SCON

Table 178. Bit Descriptions for I2C1SCON

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	STXDMA	Enable slave Tx DMA request. Set to 1 by user code to enable I2C slave DMA Rx requests. Cleared by user code to disable DMA mode.	0x0	RW
13	SRXDMA	Enable slave Rx DMA request. Set to 1 by user code to enable I2C slave DMA Rx requests. Cleared by user code to disable DMA mode.	0x0	RW
12	IENREPST	Repeated start interrupt enable. If 1 an interrupt will be generated when the REPSTART status bit asserts. If 0 an interrupt will not be generated when the REPSTART status bit asserts.	0x0	RW
11	RESERVED	Reserved.	0x0	RW
10	IENSTX	Slave Transmit request interrupt enable.	0x0	RW
9	IENSRX	Slave Receive request interrupt enable.	0x0	RW
8	IENSTOP	Stop condition detected interrupt enable.	0x0	RW
7	NACK	NACK next communication. If this bit is set the next communication will be NACK 'ed. This could be used for example if during a 24xx style access, an attempt was made to write to a 'read only' or nonexisting location in system memory. That is the indirect address in a 24xx style write pointed to an unwritable memory location.	0x0	RW
6	STRETCHSCL	Stretch SCL enable. Setting this bit tells the device if SCL is '0' hold it at '0', or if SCL is '1' then when it next goes to '0' hold it at '0'.	0x0	RW
5	EARLYTXR	Early transmit request mode. Setting this bit enables a transmit request just after the positive edge of the direction bit SCL clock pulse.	0x0	RW
4	GCSBCLR	General call status bit clear. The General Call status and General Call ID bits are cleared when a '1' is written to this bit. The General Call status and General Call ID bits are not reset by anything other than a write to this bit or a full reset.	0x0	W

Bits	Bit Name	Description	Reset	Access
3	HGCEN	Hardware general call enable. When this bit and the General Call enable bit are set the device after receiving a general call, address 00h and a data byte checks the contents of the ALT against the receive shift register. If they match the device has received a 'hardware general call'. This is used if a device needs urgent attention from a master device without knowing which master it needs to turn to, it can use this call. This is a call "to whom it may concern". The device that requires attention embeds its own address into the message. The LSB of the ALT register should always be written to a 1, as per I2C January 2000 specification.	0x0	RW
2	GCEN	General call enable. This bit enables the I2C slave to ACK an I2C general call, address 0x00 (Write).	0x0	RW
1	ADR10EN	Enabled 10-bit addressing. If this bit is clear, the slave can support four slave addresses, programmed in Register I2CID0 to Register I2CID3. When this bit is set, 10 bit addressing is enabled. One 10 bit address is supported by the slave and is stored in I2CID0 and I2CID1, where I2CID0 contains the first byte of the address and the upper 5 bits must be programmed to 11110. I2CID3 and I2CID4 can be programmed with 7 bit addresses at the same time.	0x0	RW
0	SLVEN	Slave enable. When '1' the slave is enabled. When '0' all slave state machine flops are held in reset and the slave is disabled.	0x0	RW

Slave I²C Status/Error/IRQ Register

Address: 0x4000342C, Reset: 0x0001, Name: I2C1SSTA

Table 179. Bit Descriptions for I2C1SSTA

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	START	Start and matching address. This bit is asserted if a start is detected on SCL/SDA and the device address matched, or a general call(GC - 0000_0000) code is received and GC is enabled, or a High Speed (HS - 0000_1XXX) code is received, or a start byte (0000_0001) is received. It is cleared on receipt of either a stop or start condition.	0x0	R
13	REPSTART	Repeated start and matching address. This bit is asserted if START is already asserted and then a repeated start is detected. It is cleared when read or on receipt of a STOP condition. This bit can drive an interrupt.	0x0	RC
[12:11]	IDMAT	Device ID matched. 00: Received address matched ID register 0 01: Received address matched ID register 1 10: Received address matched ID register 2 11: Received address matched ID register 3	0x0	R
10	STOP	Stop after start and matching address. Gets set by hardware if the slave device received a STOP condition after a previous START condition and a matching address. Cleared by a read of the status register. If STOPINTEN in the slave control register is asserted, then the slave interrupt request will assert when this bit is set. This bit can drive an interrupt.	0x0	RC
[9:8]	GCID	General ID. GCID is cleared when the GCSBCLR is written to 1. These status bits will not be cleared by a 'General call reset'. 00: No general call 01: General call reset and program address 10: General call program address 11: General call matching alternative ID	0x0	R
7	GCINT	General call interrupt. This bit always drives an interrupt. The bit is asserted if the slave device receives a general call of any type. To clear, write 1 to the GCSBCLR in the slave control register. If it was a general call reset, all registers will be at their default values. If it was a hardware general call, the Rx FIFO holds the second byte of the general call, and this can be compared with the ALT register.	0x0	R

Bits	Bit Name	Description	Reset	Access
6	SBUSY	Slave busy. Set by hardware if the slave device receives a I2C START condition. Cleared by hardware when the address does not match an ID register, the slave device receives a I2C STOP condition, or if a repeated start address does not match.	0x0	R
5	NOACK	ACK not generated by the slave. When asserted, it indicates that the slave responded to its device address with a NOACK. It is asserted if there was no data to transmit and sequence was a slave read or if the NACK bit was set in the slave control register and the device was addressed. This bit is cleared on a read of the I2CSSTA register.	0x0	RC
4	SRXOF	Slave Receive FIFO overflow. Asserts when a byte is written to the slave receive FIFO when the FIFO is already full.	0x0	RC
3	SRXREQ	Slave Receive request. SRXREQ asserts whenever the slave receive FIFO is not empty. Read or flush the slave receive FIFO to clear this bit. This bit will assert on the falling edge of the SCL clock pulse that clocks in the last data bit of a byte. This bit can drive an interrupt.	0x0	RC
2	STXREQ	Slave Transmit request. If EARLYTXR = 0, STXREQ is set when the direction bit for a transfer is received high. There after, as long as the transmit FIFO is not full this bit will remain asserted. Initially, it is asserted on the negative edge of the SCL pulse that clocks in the direction bit (if the device address matched also). If EARLYTXR = 1, STXREQ is set when the direction bit for a transfer is received high. There after, as long as the transmit FIFO is not full this bit will remain asserted. Initially, it is asserted after the positive edge of the SCL pulse that clocks in the direction bit (if the device address matched also). This bit is cleared on a read of the I2CSSTA register.	0x0	RC
1	STXUR	Slave Transmit FIFO underflow. Is set if a master requests data from the device, and the Tx FIFO is empty for the rising edge of SCL.	0x0	RC
0	STXFSEREQ	Slave Tx FIFO Status or early request. If EARLYTXR = 0, this bit is asserted whenever the slave Tx FIFO is empty. If EARLYTXR = 1, TXFSEREQ is set when the direction bit for a transfer is received high. It asserts on the positive edge of the SCL clock pulse that clocks in the direction bit (if the device address matched also). It only asserts once for a transfer. It is cleared when read if EARLYTXR is asserted.	0x1	RW

SERIAL PERIPHERAL INTERFACES

SPI FEATURES

Two complete hardware serial peripheral interfaces with the following standard SPI features:

- Serial clock phase mode and serial clock polarity mode
- LSB first transfer option
- Loopback mode
- Master or slave mode
- Transfer and interrupt mode
- Continuous transfer mode
- Tx/Rx FIFO
- Interrupt mode, interrupt after one, two, three, or four bytes
- Rx overflow mode and Tx underrun mode
- Open-circuit data output mode
- Full duplex communications supported (simultaneous transmit/receive)

SPI OVERVIEW

The ADuCM320 integrates two complete hardware serial peripheral interfaces (SPI). SPI is an industry-standard, synchronous serial interface that allows eight bits of data to be synchronously transmitted and simultaneously received, that is, full duplex. The two SPIs implemented on the ADuCM320 can operate to a maximum bit rate of 20 Mbps in both master and slave modes.

The SPI blocks have an additional DMA feature. Each SPI block has two DMA channels that interface with a μ DMA controller of the ARM Cortex-M3 processor. One DMA channel is used for transmitting data and the other is used for receiving data.

SPI OPERATION

The SPI port can be configured for master or slave operation and consists of four pins: MISO, MOSI, SCLK, and \overline{CS} .

Note that the GPIOs used for SPI communication must be configured in SPI mode before enabling the SPI peripheral and that the internal pull-up resistors on the SPI pins should be disabled via the GPxPUL registers when using the SPI.

MISO (Master In, Slave Out) Pin

The MISO pin is configured as an input line in master mode and an output line in slave mode. The MISO line on the master (data in) should be connected to the MISO line in the slave device (data out). The data is transferred as byte-wide (8-bit) serial data, MSB first.

MOSI (Master Out, Slave In) Pin

The MOSI pin is configured as an output line in master mode and an input line in slave mode. The MOSI line on the master (data out) should be connected to the MOSI line in the slave device (data in). The data is transferred as byte-wide (8-bit) serial data, MSB first.

SCLK (Serial Clock I/O) Pin

The master serial clock (SCLK) synchronizes the data being transmitted and received through the MOSI SCLK period. Therefore, a byte is transmitted/received after eight SCLK periods. The SCLK pin is configured as an output in master mode and as an input in slave mode.

In master mode, the polarity and phase of the clock are controlled by the SPIxCON register, and the bit rate is defined in the SPIxDIV register as follows:

$$f_{SERIALCLOCK} = \frac{SPICLK}{2 \times (1 + SPIxDIV)}$$

where $SPICLK$ is the 80 MHz system clock divided by the factor set in the CLKCON1[2:0] register.

It is possible to disable the clocks to SPI0 and SPI1 separately:

- CLKCON5[0] = 1 disables the clock to SPI0.
- CLKCON5[1] = 1 disables the clock to SPI1.

By reducing the clock rate to the SPI blocks, it is possible to reduce the power consumption of the SPI block.

The maximum data rate is 20 Mbps.

In slave mode, the SPIxCON register must be configured with the phase and polarity of the expected input clock. The slave accepts data from an external master up to 20 Mbps.

In both master and slave mode, data is transmitted on one edge of the SCLK signal and sampled on the other. Therefore, it is important that the polarity and phase be configured the same for the master and slave devices.

Chip Select (\overline{CS} Input) Pin

In SPI slave mode, a transfer is initiated by the assertion of \overline{CS} , which is an active low input signal. The SPI port then transmits and receives 8-bit data until the transfer is concluded by deassertion of \overline{CS} . In slave mode, \overline{CS} is always an input.

In SPI master mode, the \overline{CS} is an active low output signal. It asserts itself automatically at the beginning of a transfer and deasserts itself upon completion.

\overline{CS} should always be configured as an SPI pin in GPxCON when the SPI is used. If an ADuCM320 master wants to communicate with multiple SPI slaves, the \overline{CS} should be left floating and the GPIOs can be connected to the \overline{CS} lines of the slaves. The CSRSG and CSFLG bits (SPIxSTA[14] and SPIxSTA[13], respectively) can be used to determine when to pull the GPIOs low or high.

SPI TRANSFER INITIATION

In master mode, the transfer and interrupt mode bit, TIM (SPIxCON[6]), determines the manner in which an SPI serial transfer is initiated. If the TIM bit is set, a serial transfer is initiated after a write to the Tx FIFO. If the TIM bit is cleared, a serial transfer is initiated after a read of the Rx FIFO; the read must be done while the SPI interface is idle. A read done during an active transfer does not initiate another transfer.

For any setting of SPIxCON[1] and SPIxCON[6], the SPI simultaneously receives and transmits data. Therefore, during data transmission, the SPI is also receiving data and filling up the Rx FIFO. If the data is not read from the Rx FIFO, the overflow interrupt occurs when the FIFO starts to overflow. If the user does not want to read the Rx data or receive overflow interrupts, SPIxCON[12] can be set and the receive data is not saved to the Rx FIFO.

Similarly, when the user wants to only receive data and does not want to write data to the Tx FIFO, SPIxCON[13] can be set to avoid receiving underrun interrupts from the Tx FIFO.

Tx Initiated Transfer

For transfers initiated by a write to the Tx FIFO, the SPI starts transmitting as soon as the first byte is written to the FIFO, irrespective of the configuration in SPIxCON[15:14]. The first byte is immediately read from the FIFO, written to the Tx shift register, and the transfer commences.

If the continuous transfer enable bit, SPIxCON[11], is set, the transfer continues until no valid data is available in the Tx FIFO. There is no stall period between transfers where \overline{CS} is deasserted; \overline{CS} is asserted and remains asserted for the duration of the transfer until the Tx FIFO is empty. Determining when the transfer stops does not depend on SPIxCON[15:14]; the transfer stops when there is no valid data left in the FIFO. Conversely, the transfer continues while there is valid data in the FIFO.

If the continuous transfer enable bit, SPIxCON[11], is cleared, each transfer consists of a single 8-bit serial transfer. If valid data exists in the Tx FIFO, a new transfer is initiated after a stall period where \overline{CS} is deasserted.

Rx Initiated Transfer

Transfers initiated by a read of the Rx FIFO depend on the number of bytes to be received in the FIFO. If SPIxCON[15:14] = 11 and a read to the Rx FIFO occurs, the SPI initiates a 4-byte transfer. If continuous mode is set, the four bytes occur continuously with no deassertion of \overline{CS} between bytes. If continuous mode is not set, the four bytes occur with stall periods between transfers where the \overline{CS} is deasserted. A read of the Rx FIFO while the SPI is receiving data does not initiate another transfer after the present transfer is complete.

In slave mode, a transfer is initiated by the assertion of \overline{CS} ($\overline{CS} = 0$).

The device as a slave transmits and receives 8-bit data until the transfer is concluded by the deassertion of \overline{CS} ($\overline{CS} = 1$).

The SPI transfer protocol diagrams (see Figure 21 and Figure 22) illustrate the data transfer protocol for the SPI and the effects of the CPHA and CPOL bits in the control register (SPIxCON) on that protocol.

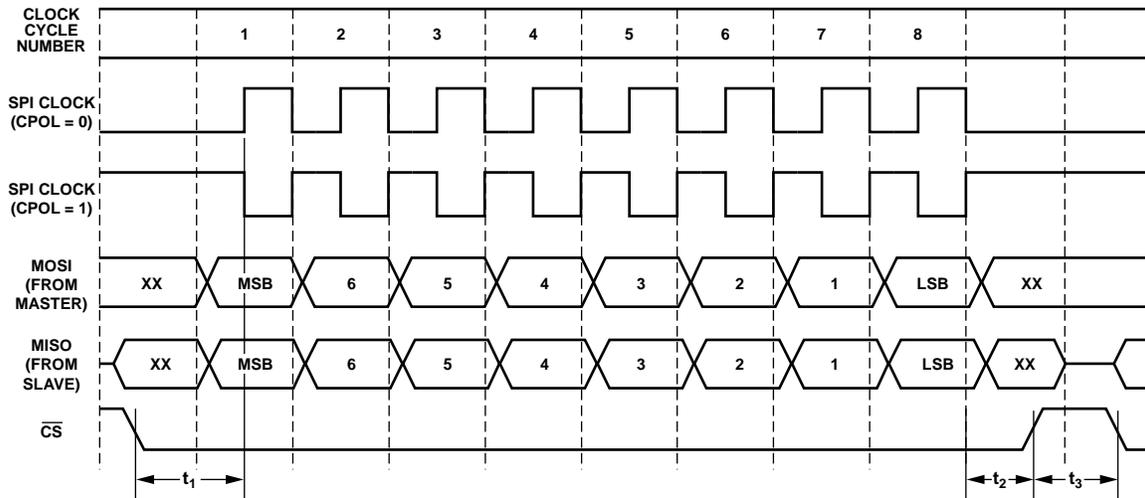

Figure 21. SPI Transfer Protocol CPHA = 0

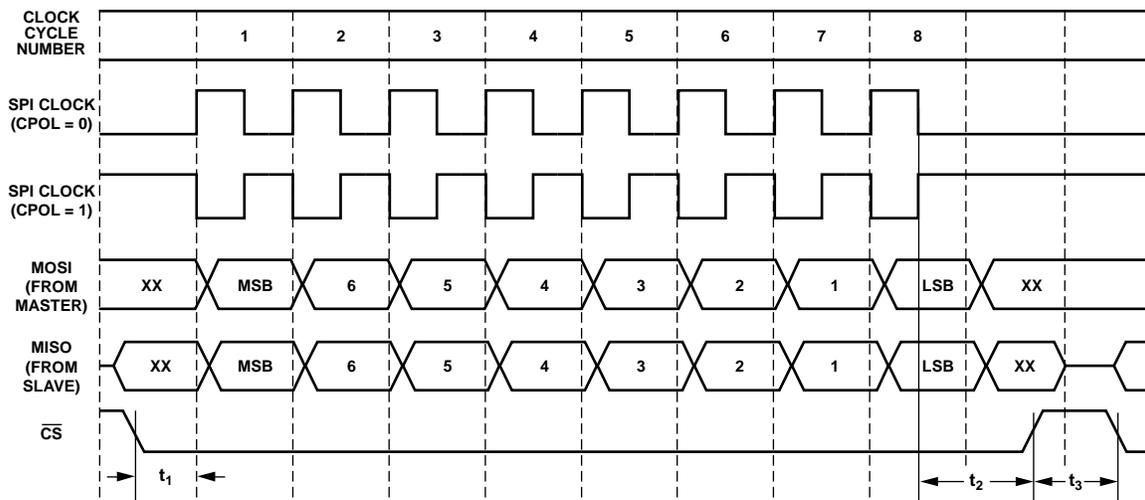

Figure 22. SPI Transfer Protocol CPHA = 1

11176-025

11176-026

SPI Data Underrun and Overflow

If the transmit zeros enable bit, ZEN (SPIxCON[7]), is cleared, the last byte from the previous transmission is shifted out when a transfer is initiated with no valid data in the FIFO. If ZEN is set to 1, 0s are transmitted when a transfer is initiated with no valid data in the FIFO.

If the Rx overflow overwrite enable bit, RXOF (SPIxCON[8]), is set, the valid data in the Rx FIFO is overwritten by the new serial byte received if there is no space left in the FIFO. If RXOF is cleared, the new serial byte received is discarded if there is no space left in the FIFO.

When the RXOF is set, the contents of the SPI Rx FIFO are undefined and its contents should be discarded by user code.

Full Duplex Operation

Simultaneous reads/writes are supported on the SPI.

When implementing full duplex transfers in master mode, use the following procedure:

1. Initiate a transfer sequence via a transmit on the MOSI pin. Set SPIxCON[6] = 1. If interrupts are enabled, interrupts are triggered when a transmit interrupt occurs but not when a byte is received.
2. If you are using interrupts, the SPI Tx interrupt indicated by SPIxSTA[5] or the Tx FIFO underrun interrupt (SPIxSTA[4]) is asserted approximately 3 × SPICLK to 4 × SPICLK periods into the transfer of the first byte. Reload a byte into the Tx FIFO, if necessary, by writing to SPIxTX.
3. The first byte received via the MISO pin does not update the Rx FIFO status bits (SPIxSTA[10:8]) until 12 × SPICLK periods after CS has gone low. Therefore, two transmit interrupts may occur before the first receive byte is ready to be handled.
4. After the last transmit interrupt has occurred, it may be necessary to read two more bytes. It is recommended that SPIxSTA[10:8] are polled outside of the SPI interrupt handler after the last transmit interrupt is handled.

SPI INTERRUPTS

There is one interrupt line per SPI and four sources of interrupts. SPIxSTA[0] reflects the state of the interrupt line, and SPIxSTA[7:4] reflects the state of the four sources.

The SPI generates either TIRQ or RIRQ. Both interrupts cannot be enabled at the same time. The appropriate interrupt is enabled using the TIM bit, SPIxCON[6]. If TIM = 1, TIRQ is enabled. If TIM = 0, RIRQ is enabled.

In addition, note that the SPI0 and SPI1 interrupt source must be enabled in the NVIC register as follows: ISER0[19] = SPI0, ISER0[20] = SPI1.

Tx Interrupt

If TIM (SPIxCON[6]) is set, the Tx FIFO status causes the interrupt. The SPIxCON[15:14] bits control when the interrupt occurs, as shown in Table 189.

Table 189. SPIxCON[15:14] IRQ Mode Bits

SPIxCON[15:14]	Interrupt Condition
00	An interrupt is generated after each byte that is transmitted. The interrupt occurs when the byte is read from the FIFO and written to the shift register.
01	An interrupt is generated after every two bytes that are transmitted.
10	An interrupt occurs after every third byte that is transmitted.
11	An interrupt occurs after every fourth byte that is transmitted.

The interrupts are generated depending on the number of bytes transmitted and not on the number of bytes in the FIFO. This is unlike the Rx interrupt, which depends on the number of bytes in the Rx FIFO and not the number of bytes received.

The transmit interrupt is cleared by a read to the status register. The status of this interrupt can be read by reading SPIxSTA[5]. The interrupt is disabled if SPIxCON[13] is left high.

A write to the control register, SPIxCON, resets the transmitted byte counter back to 0. For example, in a case where SPIxCON[15:14] is set to 0x3 and SPIxCON is written to after three bytes have been transmitted, the Tx interrupt does not occur until another four bytes have been transmitted.

Rx Interrupt

If TIM (SPIxCON[6]) is cleared, the Rx FIFO status causes the interrupt. The SPIxCON[15:14] bits control when the interrupt occurs. The interrupt is cleared by a read of SPIxSTA. The status of this interrupt can be read by reading SPIxSTA[6].

Interrupts are only generated when data is written to the FIFO. For example, if the SPIxCON[15:14] bits are set to 0x00, an interrupt is generated after the first byte is received. When the status register is read, the interrupt is deactivated. If the byte is not read from the FIFO, the interrupt is not regenerated. Another interrupt is not generated until another byte is received in the FIFO.

The interrupt depends on the number of valid bytes in FIFO and not the number of bytes received. For example, when the SPIxCON[15:14] bits are set to 0x1, an interrupt is generated after a byte is received if there are two or more bytes in the FIFO. The interrupt is not generated after every two bytes received.

The interrupt is disabled if SPIxCON[12] is left high.

Underrun/Overflow Interrupts

SPIxSTA[7] and SPIxSTA[4] generate SPI interrupts.

When a transfer starts with no data in the Tx FIFO, SPIxSTA[4] is set to indicate an underrun condition. This causes an interrupt. The interrupt (and status bit) are cleared upon a read of the status register. This interrupt occurs irrespective of SPIxCON[15:14]. This interrupt is disabled if SPIxCON[13] is set.

When data is received and the Rx FIFO is already full, SPIxSTA[7] is set to 1, indicating an overflow condition. This causes an interrupt. The interrupt (and status bit) are cleared upon a read of the status register. This interrupt occurs irrespective of SPIxCON[15:14]. This interrupt is disabled if SPIxCON[12] is set.

When the SPI Rx overflow bit (SPIxSTA[7]) is set to 1, the contents of the SPI Rx FIFO are undetermined and should not be used. The user should flush the Rx FIFO upon detecting this error condition.

All interrupts are cleared either by a read of the status register or when SPIxCON[0] is deasserted. The Rx and Tx interrupts are also cleared if the relevant flush bits are asserted. Otherwise, the interrupts stay active even if the SPI is reconfigured.

SPI WIRE-OR'ED MODE (WOM)

To prevent contention when the SPI is used in a multimaster or multislave system, the data output pins, MOSI and MISO, can be configured to behave as open-circuit drivers. An external pull-up resistor is required when this feature is selected. The WOM bit (SPIxCON[4]) controls the pad enable outputs for the data lines.

SPI CSERR CONDITION

The CSERR bit (SPIxSTA[12]) indicates if an erroneous deassertion of the \overline{CS} signal has been detected before the completion of all eight SCLK cycles. This bit generates an interrupt and is available in all modes of operation: slave, master, and during DMA transfers.

If an interrupt generated by the CSERR bit (SPIxSTA[12]) occurs, the SPI ENABLE bit (SPIxCON[0]) should be disabled and restarted to enable a clean recovery. This ensures that subsequent transfers are error free. The BCRST bit (SPIxDIV[7]) should be set at all times in both slave mode and master mode except when a midbyte stall in SPI communication is required. In this case, the CSERR flag is set but can be ignored.

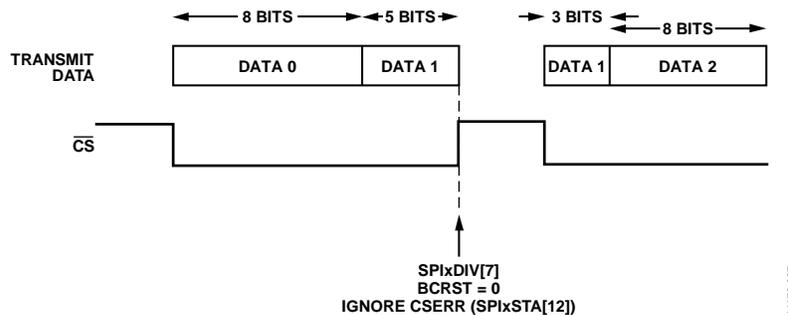

Figure 23. SPI Communication: Midbyte Stall

Note that the SPI should only be reenabled when the \overline{CS} signal is high.

SPI DMA

DMA operation is provided on both SPI channels. Two DMA channels are dedicated to transmit and receive. The SPI DMA channels should be configured in the μ DMA controller of the ARM Cortex-M3 processor.

It is possible to enable a DMA request on one or two channels at the same time by setting the DMA request bits for receive or transmit in the SPIxDMA register. If only the DMA transmit request (SPIxDMA[1]) is enabled, the Rx FIFO overflows during an SPI transfer, unless the received data is read by user code, and an overflow interrupt is generated. To avoid generating overflow interrupts, the Rx FIFO flush bit should be set or the SPI interrupt should be disabled in the NVIC. If only the DMA receive request (SPIxDMA[2]) is enabled, the Tx FIFO is underrun. To avoid an underrun interrupt, the SPI interrupt should be disabled.

The SPI Tx (SPIxSTA[5]) and SPI Rx (SPIxSTA[6]) interrupts are not generated when using DMA. The SPI TXUR (SPIxSTA[4]) and RXOF (SPIxSTA[7]) interrupts are generated when using DMA. The SPIxCON[15:14] bits are not used in transmit mode and should be set to 0x00 in receive mode.

The enable bit (SPIxDMA[0]) controls the start of a DMA transfer. DMA requests are only generated when enable = 1. At the end of a DMA transfer, that is, when receiving a DMA SPI transfer interrupt, this bit needs to be cleared to prevent extra DMA requests to the μ DMA controller. The data still present in the Tx FIFO is transmitted if in Tx mode.

DMA Master Transmit Configuration

The DMA SPI Tx channel should be configured.

The NVIC should be configured to enable DMA Tx master interrupt (for example, enable DMA Tx master interrupt SPI0 Tx using ISER0[26]).

When all data present in the DMA buffer are transmitted, the DMA generates an interrupt. User code should disable the DMA request. Data is still in the Tx FIFO because the DMA request is generated each time there is free space in the Tx FIFO to always keep the FIFO full. User code can check how many bytes are still present in the FIFO in the FIFO status register.

DMA Master Receive Configuration

The SPIxCNT register is available in DMA receive master mode only. It sets the number of receive bytes required by the SPI master or the number of clocks that the master needs to generate. When the required number of bytes are received, no more transfers are initiated. To initiate a DMA master receive transfer, a dummy read should be completed by user code. This dummy read should be added to the SPIxCNT number.

The counter counting the bytes as they are received is reset either when SPI is disabled in SPIxCON[0] or if the SPIxCNT register is modified by user code.

Performing SPIx DMA Master Receive

The DMA SPI Rx channel should be configured.

The NVIC should be configured to enable DMA Rx master interrupt (for example, enable DMA Rx master interrupt SPI1 Rx using ISER0[29]).

The DMA transfer stops when the number of bytes have been transferred. Note that the DMA buffer must be of the same size as SPIxCNT to generate a DMA interrupt when the transfer is complete.

SPI AND POWER-DOWN MODES

In master mode, before entering power-down mode it is recommended to disable the SPI block in SPIxCON[0]. In slave mode, in either mode of operation, interrupt driven or DMA, the $\overline{\text{CS}}$ line level should be checked via the GPIO registers to ensure that the SPI is not communicating and that the SPI block is disabled while the $\overline{\text{CS}}$ line is high. At power-up, the SPI block can be reenabled.

REGISTER SUMMARY: SPI0**Table 190. SPI0 Register Summary**

Address	Name	Description	Reset	RW
0x4002C000	SPI0STA	Status register	0x0000	R
0x4002C004	SPI0RX	Receive register	0x0000	R
0x4002C008	SPI0TX	Transmit register	0x0000	W
0x4002C00C	SPI0DIV	Baud rate selection register	0x0000	RW

REGISTER DETAILS: SPI0**Status Register**

Address: 0x4002C000, Reset: 0x0000, Name: SPI0STA

Table 191. Bit Descriptions for SPI0STA

Bits	Bit Name	Description	Reset	Access
15	RESERVED		0x0	R
14	CSRSG	Detected a rising edge on CS, in CONT mode. This bit will cause an interrupt. This can be used to identify the end of an SPI data frame. 0: Cleared to 0 when the Status register is read. 1: Set to 1 when there was a rising edge in CS line, when the device was in master mode, continuous transfer, High Frequency mode and CSIRQ_EN was asserted.	0x0	RC
13	CSFLG	Detected a falling edge on CS, in CONT mode. This bit will cause an interrupt. This can be used to identify the start of an SPI data frame. 0: Cleared to 0 when the Status register is read. 1: Set to 1 when there was a falling edge in CS line, when the device was in master mode, continuous transfer, High Frequency mode and CSIRQ_EN was asserted	0x0	RC
12	CSERR	Detected a CS error condition. 0: Cleared to 0 when the Status register is read. 1: Set to 1 when the CS line was de-asserted abruptly, even before the full-byte of data was transmitted completely. This bit will cause an interrupt.	0x0	RC
11	RXS	SPI Rx FIFO excess bytes present. 0: This bit is cleared when the number of bytes in the FIFO is equal or less than the number in SPI0CON[15:14]. 1: This bit is set when there are more bytes in the Rx FIFO than indicated in the MOD bits in SPI0CON.	0x0	R
[10:8]	RXFSTA	SPI Rx FIFO status. 000: Rx FIFO empty 001: 1 valid byte in FIFO 010: 2 valid bytes in the FIFO 011: 3 valid bytes in the FIFO 100: 4 valid bytes in the FIFO	0x0	R
7	RXOF	SPI Rx FIFO overflow. 0: Cleared when the SPISTA register is read. 1: Set when the Rx FIFO was already full when new data was loaded to the FIFO. This bit generates an interrupt except when RFLUSH is set in SPI0CON.	0x0	RC
6	RX	SPI Rx IRQ. Not available in DMA mode. 0: Cleared when the SPI0STA register is read. 1: Set when a receive interrupt occurs. This bit is set when TIM in SPI0CON is cleared and the required number of bytes have been received.	0x0	RC

Bits	Bit Name	Description	Reset	Access
5	TX	SPI Tx IRQ. Status Bit. Not available in DMA mode. 0: CLR. Cleared to 0 when the SPI0STA register is read. 1: SET. Set to 1 when a transmit interrupt occurs. This bit is set when TIM in SPI0CON is set and the required number of bytes have been transmitted.	0x0	RC
4	TXUR	SPI Tx FIFO underflow. 0: Cleared to 0 when the SPI0STA register is read. 1: Set to 1 when a transmit is initiated without any valid data in the Tx FIFO. This bit generates an interrupt except when TFLUSH is set in SPI0CON.	0x0	RC
[3:1]	TXFSTA	SPI Tx FIFO status. 000: Tx FIFO empty 001: 1 valid byte in FIFO 010: 2 valid bytes in FIFO 011: 3 valid bytes in FIFO 100: 4 valid bytes in FIFO	0x0	R
0	IRQ	SPI Interrupt status. 0: Cleared to 0 after reading SPI0STA. 1: Set to 1 when an SPI based interrupt occurs.	0x0	RC

Receive Register

Address: 0x4002C004, Reset: 0x0000, Name: SPI0RX

Table 192. Bit Descriptions for SPI0RX

Bits	Bit Name	Description	Reset	Access
[15:8]	DMA_DATA_BYTE_2	8-bit receive buffer. These 8-bits are used only in the DMA mode, where all FIFO accesses happen as half-word access. They return zeros if DMA is disabled.	0x0	R
[7:0]	DATA_BYTE_1	8-bit receive buffer.	0x0	R

Transmit Register

Address: 0x4002C008, Reset: 0x0000, Name: SPI0TX

Table 193. Bit Descriptions for SPI0TX

Bits	Bit Name	Description	Reset	Access
[15:8]	DMA_DATA_BYTE_2	8-bit transmit buffer. These 8-bits are used only in the DMA mode, where all FIFO accesses happen as half-word access. They return zeros if DMA is disabled.	0x0	W
[7:0]	DATA_BYTE_1	8-bit transmit buffer.	0x0	W

Baud Rate Selection Register

Address: 0x4002C00C, Reset: 0x0000, Name: SPI0DIV

Table 194. Bit Descriptions for SPI0DIV

Bits	Bit Name	Description	Reset	Access
[15:9]	RESERVED		0x0	R
8	CSIRQ_EN	Enable interrupt on every CS edge in CONT mode. If this bit is set and the SPI module is in continuous mode, any edge on CS will generate an interrupt and the corresponding status bits(CSRSG, CSFLG) will be asserted. If this bit is clear, then no interrupt will be generated. This bit has no effect if the SPI is not in continuous mode.	0x0	RW
7	BCRST	Reset Mode for CSERR. If this bit is set, the bit counter will be reset after a CS error condition and the Cortex is expected to clear the SPI enable bit. If this bit is clear, the bit counter will continue from where it stopped. SPI can receive the remaining bits when CS gets asserted and Cortex has to ignore the CSERR interrupt. However, it is strongly recommended to set this bit for a graceful recovery after a CS error.	0x0	RW

Bits	Bit Name	Description	Reset	Access
6	HFM	High Frequency Mode. This bit is used for applications using high frequency where the pad introduces a significant delay on the SCL. This can cause a significant enough difference between the serial clock and the data being received on the Rx shift register. In this mode, the Rx shift register is clocked by SCLIN instead of UCLK.	0x0	RW
[5:0]	DIV	SPI clock divider. DIV is the factor used to divide UCLK to generate the serial clock.	0x0	RW

SPI Configuration Register

Address: 0x4002C010, Reset: 0x0000, Name: SPI0CON

Table 195. Bit Descriptions for SPI0CON

Bits	Bit Name	Description	Reset	Access
[15:14]	MOD	SPI IRQ mode bits. These bits configure when the Tx/Rx interrupts occur in a transfer. For DMA Rx transfer, these bits should be 00. 00: Tx interrupt occurs when 1 byte has been transferred. Rx interrupt occurs when 1 or more bytes have been received into the FIFO. 01: Tx interrupt occurs when 2 bytes has been transferred. Rx interrupt occurs when 2 or more bytes have been received into the FIFO. 10: Tx interrupt occurs when 3 bytes has been transferred. Rx interrupt occurs when 3 or more bytes have been received into the FIFO. 11: Tx interrupt occurs when 4 bytes has been transferred. Rx interrupt occurs when the Rx FIFO is full, or 4 bytes present.	0x0	RW
13	TFLUSH	SPI Tx FIFO Flush enable. 0: Clear this bit to disable Tx FIFO flushing. 1: Set this bit to flush the Tx FIFO. This bit does not clear itself and should be toggled if a single flush is required. If this bit is left high, then either the last transmitted value or "0x00" is transmitted depending on the ZEN bit. Any writes to the Tx FIFO are ignored while this bit is set.	0x0	RW
12	RFLUSH	SPI Rx FIFO Flush enable. 0: Clear this bit to disable Rx FIFO flushing. 1: Set this bit to flush the Rx FIFO. This bit does not clear itself and should be toggled if a single flush is required. If this bit is set all incoming data is ignored and no interrupts are generated. If set and TIM = 0, a read of the Rx FIFO will initiate a transfer.	0x0	RW
11	CON	Continuous transfer enable. 0: DIS. Cleared by user to disable continuous transfer. Each transfer consists of a single 8-bit serial transfer. If valid data exists in the SPI0TX register, then a new transfer is initiated after a stall period of 1 serial clock cycle. 1: EN. Set by user to enable continuous transfer. In master mode, the transfer continues until no valid data is available in the Tx register. CS is asserted and remains asserted for the duration of each 8-bit serial transfer until Tx is empty.	0x0	RW
10	LOOPBACK	Loopback enable. 0: Cleared by user to be in normal mode. 1: Set by user to connect MISO to MOSI and test software.	0x0	RW
9	OEN	Slave MISO output enable. 0: Clear this bit to disable the output driver on the MISO pin. The MISO pin will be Open-Circuit when this bit is clear. 1: Set this bit for MISO to operate as normal.	0x0	RW
8	RXOF	SPIRX overflow overwrite enable. 0: Cleared by user, the new serial byte received is discarded. 1: Set by user, the valid data in the Rx register is overwritten by the new serial byte received.	0x0	RW

Bits	Bit Name	Description	Reset	Access
7	ZEN	Transmit zeros enable. 0: Clear this bit to transmit the last transmitted value when there is no valid data in the Tx FIFO. 1: Set this bit to transmit "0x00" when there is no valid data in the Tx FIFO.	0x0	RW
6	TIM	SPI transfer and interrupt mode. 0: Cleared by user to initiate transfer with a read of the SPI0RX register. Interrupt only occurs when Rx is full. 1: Set by user to initiate transfer with a write to the SPI0TX register. Interrupt only occurs when Tx is empty.	0x0	RW
5	LSB	LSB first transfer enable. 0: MSB transmitted first 1: LSB transmitted first	0x0	RW
4	WOM	SPI Wired Or mode. 1: Enables open circuit data output enable. External pull-ups required on data out pins 0: Normal output levels	0x0	RW
3	CPOL	Serial Clock Polarity. 0: Serial clock idles low 1: Serial clock idles high	0x0	RW
2	CPHA	Serial clock phase mode. 1: Serial clock pulses at the beginning of each serial bit transfer 0: Serial clock pulses at the end of each serial bit transfer	0x0	RW
1	MASEN	Master mode enable. 0: Enable slave mode 1: Enable master mode	0x0	RW
0	ENABLE	SPI enable. 0: Disable the SPI 1: Enable the SPI	0x0	RW

SPI DMA Enable Register

Address: 0x4002C014, Reset: 0x0000, Name: SPI0DMA

Table 196. Bit Descriptions for SPI0DMA

Bits	Bit Name	Description	Reset	Access
[15:3]	RESERVED		0x0	R
2	IENRXDMA	Enable receive DMA request. 0: Disable RX DMA Interrupt 1: Enable RX DMA Interrupt	0x0	RW
1	IENTXDMA	Enable transmit DMA request. 0: Disable TX DMA Interrupt 1: Enable TX DMA Interrupt	0x0	RW
0	ENABLE	Enable DMA for data transfer. Set by user code to start a DMA transfer. Cleared by user code at the end of DMA transfer. This bit needs to be cleared to prevent extra DMA request to the uDMA controller.	0x0	RW

Transfer Byte Count Register

Address: 0x4002C018, Reset: 0x0000, Name: SPI0CNT

Table 197. Bit Descriptions for SPI0CNT

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	COUNT	Transfer byte count. COUNT indicates the number of bytes to be transferred. Count is used in both receive and transmit transfer types. The COUNT value assures that a master mode transfer terminates at the proper time and that 16-bit DMA transfers are byte padded or discarded as required to match odd transfer counts. Reset by clearing SPI0CON[0] or if SPI0CNT is updated.	0x0	RW

If set and TIM = 0, a read of the Rx FIFO will initiate a transfer.	0x0	RW

Bits	Bit Name	Description	Reset	Access
11	CON	Continuous transfer enable. 0: DIS. Cleared by user to disable continuous transfer. Each transfer consists of a single 8-bit serial transfer. If valid data exists in the SPI1TX register, then a new transfer is initiated after a stall period of 1 serial clock cycle. 1: EN. Set by user to enable continuous transfer. In master mode, the transfer continues until no valid data is available in the Tx register. CS is asserted and remains asserted for the duration of each 8-bit serial transfer until Tx is empty.	0x0	RW
10	LOOPBACK	Loopback enable. 0: Cleared by user to be in normal mode. 1: Set by user to connect MISO to MOSI and test software.	0x0	RW
9	OEN	Slave MISO output enable. 0: Clear this bit to disable the output driver on the MISO pin. The MISO pin will be Open-Circuit when this bit is clear. 1: Set this bit for MISO to operate as normal.	0x0	RW
8	RXOF	SPIRX overflow overwrite enable. 0: Cleared by user, the new serial byte received is discarded. 1: Set by user, the valid data in the Rx register is overwritten by the new serial byte received.	0x0	RW
7	ZEN	Transmit zeros enable. 0: Clear this bit to transmit the last transmitted value when there is no valid data in the Tx FIFO. 1: Set this bit to transmit "0x00" when there is no valid data in the Tx FIFO.	0x0	RW
6	TIM	SPI transfer and interrupt mode. 0: Cleared by user to initiate transfer with a read of the SPIRX register. Interrupt only occurs when Rx is full. 1: Set by user to initiate transfer with a write to the SPITX register. Interrupt only occurs when Tx is empty.	0x0	RW
5	LSB	LSB first transfer enable. 0: MSB transmitted first 1: LSB transmitted first	0x0	RW
4	WOM	SPI Wired Or mode. 0: Normal output levels 1: Enables open circuit data output enable. External pull-ups required on data out pins	0x0	RW
3	CPOL	Serial Clock Polarity. 0: Serial clock idles low 1: Serial clock idles high	0x0	RW
2	CPHA	Serial clock phase mode. 0: Serial clock pulses at the end of each serial bit transfer 1: Serial clock pulses at the beginning of each serial bit transfer	0x0	RW
1	MASEN	Master mode enable. 0: Enable slave mode 1: Enable master mode	0x0	RW
0	ENABLE	SPI enable. 0: Disable the SPI 1: Enable the SPI	0x0	RW

SPI DMA Enable Register

Address: 0x40030014, Reset: 0x0000, Name: SPI1DMA

Table 204. Bit Descriptions for SPI1DMA

Bits	Bit Name	Description	Reset	Access
[15:3]	RESERVED		0x0	R
2	IENRXDMA	Enable receive DMA request. 0: Disable RX DMA Interrupt 1: Enable RX DMA Interrupt	0x0	RW
1	IENTXDMA	Enable transmit DMA request. 0: Disable TX DMA Interrupt 1: Enable TX DMA Interrupt	0x0	RW
0	ENABLE	Enable DMA for data transfer. Set by user code to start a DMA transfer. Cleared by user code at the end of DMA transfer. This bit needs to be cleared to prevent extra DMA request to the uDMA controller.	0x0	RW

Transfer Byte Count Register

Address: 0x40030018, Reset: 0x0000, Name: SPI1CNT

Table 205. Bit Descriptions for SPI1CNT

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	COUNT	Transfer byte count. COUNT indicates the number of bytes to be transferred. Count is used in both receive and transmit transfer types. The COUNT value assures that a master mode transfer terminates at the proper time and that 16-bit DMA transfers are byte padded or discarded as required to match odd transfer counts. Reset by clearing SPI1CON[0] or if SPI1CNT is updated.	0x0	RW

UART SERIAL INTERFACE

UART FEATURES

- Industry-standard 16,450 UART peripheral
- Support for DMA

UART OVERVIEW

The UART peripheral is a full-duplex universal asynchronous receiver/transmitter (UART), compatible with the industry-standard 16,450. The UART is responsible for converting data between serial and parallel formats. The serial communication follows an asynchronous protocol, supporting various word lengths, stop bits, and parity generation options.

This UART also contains interrupt handling hardware. The UART features a fractional divider that facilitates high accuracy baud rate generation.

Interrupts can be generated from several unique events, such as full/empty data buffer, transfer error detection, and break detection.

UART OPERATION

Serial Communications

An asynchronous serial communication protocol is followed with these options:

- 5 to 8 data bits
- 1, 2, or 1½ stop bits
- None, even, or odd parity
- The baud rate is as follows:

$$\text{Baud Rate} = \text{UCLK/CDPCLK} \div (2 \times 16 \times \text{COMDIV}) \div (M + N \div 2048)$$

where:

$\text{COMDIV} = 1$ to 65,536.

$M = 1$ to 3.

$N = 0$ to 2047.

UCLK/CDPCLK is the divided 80 MHz clock as configured via $\text{CLKCON1}[10:8]$

All data-words require a start bit and at least one stop bit. This creates a range from seven bits to twelve bits for each word. Transmit operation is initiated by writing to the transmit holding register (COMTX). After a synchronization delay, the data is moved to the internal transmit shift register (TSR), where it is shifted out at a baud (bit) rate equal to the following with start, stop, and parity bits appended as required:

$$\text{UCLK/CDPCLK} \div (2 \times 16 \times \text{COMDIV}) \div (M + N \div 2048)$$

All data-words begin with a low-going start bit. The transfer of COMTX to the TSR causes the transmit register empty status flag to be set.

The receive operation uses the same data format as the transmit configuration except for the number of stop bits, which is always one. After detection of the start bit, the received word is shifted into the internal receive shift register (RSR). After the appropriate number of bits (including stop bits) are received, the data and any status are updated, and the RSR is transferred to the receive buffer register (COMRX). The receive buffer register full status flag is updated upon the transfer of the received word to this buffer and the appropriate synchronization delay.

A sampling clock equal to 16 times the baud rate is used to sample the data as close to the midpoint of the bit as possible. A receive filter is also present that removes spurious pulses of less than two times the sampling clock period.

Note that data is transmitted and received least significant bit first. This is often not the assumed case by the user. However, it is standard for the protocol.

For power saving purposes, it is possible to disable the system clock to the UART via the $\text{CLKCON5}[5]$ register. By default, the clock to the UART is disabled ($\text{CLKCON5}[5] = 1$).

Programmed I/O Mode

In this mode, the software is responsible for moving data to and from the UART. This is typically accomplished by interrupt service routines that respond to the transmit and receive interrupts by either reading or writing data as appropriate. This mode puts certain constraints on the software itself in that the software must respond within a certain time to prevent overflow errors from occurring in the receive channel.

Polling the status flag is processor intensive and not typically used unless the system can tolerate the overhead. Interrupts can be disabled using the COMIEN register.

Writing COMTX when it is not empty or reading COMRX when it is not full produces incorrect results and should not be done. In the former case, COMTX is overwritten by the new word, and the previous word is never transmitted. In the latter case, the previously received word is read again. Both of these errors must be avoided in software by correctly using either interrupts or status register polling. These errors are not detected in hardware.

Enable/Disable Bit

Before the ADuCM320 enters power-down mode, it is recommended to disable the serial interfaces. A bit is provided in the UART control register to disable the UART serial peripheral. This bit disables the clock to the peripheral. When setting this bit, care must be taken in software that no data is being transmitted or received. If this bit is set during communication, the data transfer does not complete; the receive or transmit register contains only part of the data.

Interrupts

The UART peripheral has one interrupt output to the interrupt controller for both Rx and Tx interrupts. The COMIIR register must be read by software to determine the cause of the interrupt. Note that in DMA mode the break interrupt is not available.

In I/O mode when receiving, the interrupt is generated for the following cases:

- COMRX full
- Receive overflow error
- Receive parity error
- Receive framing error
- Break interrupt (UART RxD held low)
- COMTX empty

Buffer Requirements

This UART is double buffered (holding register and shift register).

DMA Mode

In this mode, user code does not move data to and from the UART. DMA request signals going to the external DMA block indicate that the UART is ready to transmit or receive data. These DMA request signals can be disabled in the COMIEN register.

Example Code to Set Up UART Receive DMA Channel

```
void UARTRXDMAINIT(void)
{
    NVIC_EnableIRQ(DMA_UART_RX_IRQn);           // Uart Tx DMA interrupt enable
    pADI_UART->COMLCR = COMLCR_WLS_EIGHTBITS | COMLCR_STOP; // 8 data bits + 1 stop bit
    pADI_UART->COMDIV = 0x41;                     // Set UART baud rate
    pADI_UART->COMFBR = COMFBR_FBEN_EN | 0x803;   // DIVM = 1, DIVN = 3
    pADI_GP1->GPCON = 0x5;                       // Configure P1.0/P1.1 for UART
    Dma_Init();
    pADI_DMA->DMACFG = 0x1;
    UARTRXDMAINIT(uxUARTRXData, 4);             // Enable DMA mode in DMA controller
    pADI_DMA->DMAENSET = 0x20;                   // Enable UART_RX_DMA Channel
    pADI_UART->COMIEN = 0x20;                     // Enable DMA Rx transfers
}

void UARTRXDMAINIT(unsigned char *pucRX_DMA, unsigned int iNumVals)
{
    DmaDesc Desc;
    // Common configuration of all the descriptors used here
    Desc.ctrlCfg.bits.cycle_ctrl = DMA_BASIC;

REGISTER DETAILS: UART**Transmit Holding Register**

Address: 0x40005000, Reset: 0x0000, Name: COMTX

COMRX and COMTX share the same address while they are implemented as different registers. If these registers are written to, the user accesses the transmit holding register (COMTX). If these registers are read from, the user accesses the receive buffer register (COMRX)

Table 207. Bit Descriptions for COMTX

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	THR	Transmit Holding Register. This is an 8-bit register to which the user can write the data to be sent. If the ETBEI bit is set in the COMIEN register, an interrupt is generated when COMTX is empty. If user code sets ETBEI while COMTX is already empty, an interrupt is generated immediately.	0x0	W

Receive Buffer Register

Address: 0x40005000, Reset: 0x0000, Name: COMRX

Table 208. Bit Descriptions for COMRX

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
[7:0]	RBR	Receive Buffer Register. This is an 8-bit register from which the user can read received data. If the ERBFI bit is set in the COMIEN register, an interrupt is generated when this register is fully loaded with the received data via serial input port. If user code sets the ERBFI bit while COMRX is already full, an interrupt is generated immediately.	0x0	R

Interrupt Enable Register

Address: 0x40005004, Reset: 0x0000, Name: COMIEN

COMIEN is the interrupt enable register that is used to configure which interrupt source generates the interrupt. Only the lowest four bits in this register enable interrupts. Bit 4 and Bit 5 enable UART DMA signals. The UART DMA channel and interrupt must be configured in the DMA block.

Table 209. Bit Descriptions for COMIEN

Bits	Bit Name	Description	Reset	Access

[15:0]	DIV	Baud rate divider. The COMDIV register should not be 0, which is not specified. The range of allowed DIV values is from 1 to 65535.	0x1	RW

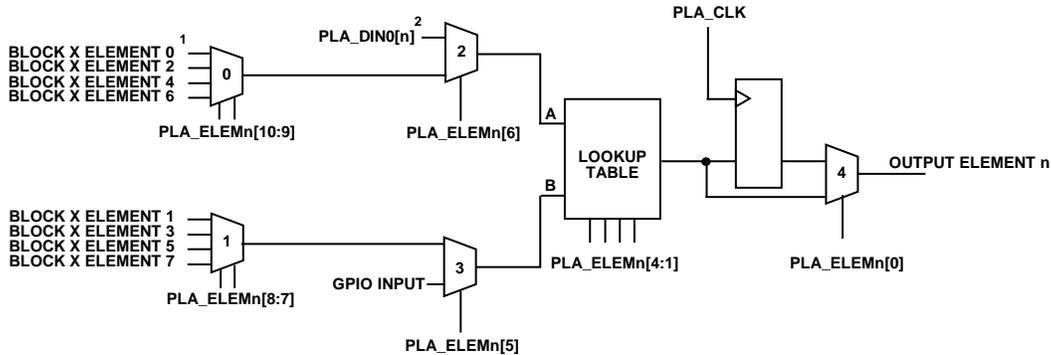

PLA

PLA FEATURES

The ADuCM320 integrates a fully programmable logic array (PLA) that consists of four independent but interconnected PLA blocks. Each block consists of eight PLA elements: Block X Element 0 to Block X Element 7, where X is the block number. Each ADuCM320 has four blocks, resulting in a total of 32 PLA elements: Element 0 to Element 31.

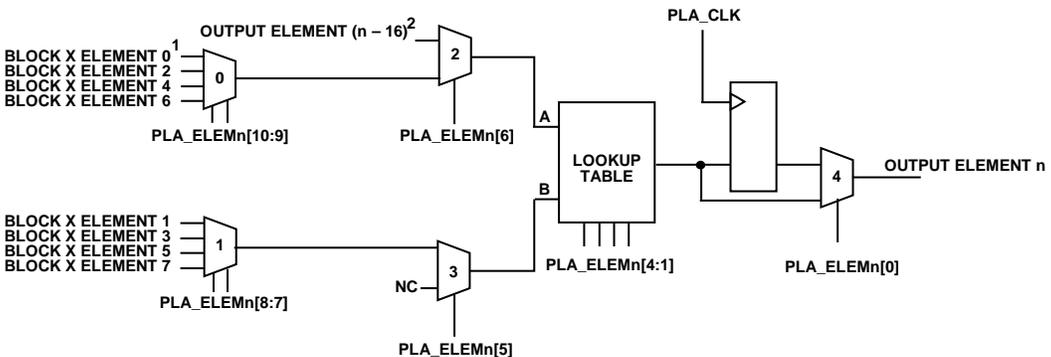

PLA OVERVIEW

Each PLA element contains a two-input lookup table that can be configured to generate any logic output function based on two inputs and a flip-flop.

WHERE:
 BLOCK X IS BLOCK 0 OR BLOCK 1.
 PLA_ELEMn IS THE MMR CONTROLLING ELEMENT n, n = 0 TO 15.
 NC = NO CONNECTION.
 1THE FIRST SELECTION OF MUX0 IS THE FEEDBACK FROM BLOCK X ELEMENT 0, WHERE X IS THE NUMBER OF THE CURRENT BLOCK. IF THE FIRST ELEMENT IN THE BLOCK IS BEING CONFIGURED, THEN THE FEEDBACK COMES FROM ANOTHER BLOCK. SEE THE INTERBLOCK CONNECTION DIAGRAM FOR MORE DETAILS.
 2BLOCK 0 AND BLOCK 1 ARE SET IN THE CORRESPONDING BIT IN THE PLA_DIN0 MMR.

Figure 24. PLA Element: Block 0 and Block 1

WHERE:
 BLOCK X IS BLOCK 2 OR BLOCK 3.
 PLA_ELEMn IS THE MMR CONTROLLING ELEMENT n, n = 16 TO 31.
 NC = NO CONNECTION.
 1THE FIRST SELECTION OF MUX0 IS THE FEEDBACK FROM BLOCK X ELEMENT 0, WHERE X IS THE NUMBER OF THE CURRENT BLOCK. IF THE FIRST ELEMENT IN THE BLOCK IS BEING CONFIGURED, THEN THE FEEDBACK COMES FROM ANOTHER BLOCK. SEE THE INTERBLOCK CONNECTION DIAGRAM.
 2FOR BLOCK 2 AND BLOCK 3 THE INPUT COMES FROM THE OUTPUT OF ELEMENT(n - 16), WHERE n IS THE NUMBER OF THE ELEMENT BEING CONFIGURED. FOR EXAMPLE, FOR ELEMENT 25 THE INPUT TO MUX 2 COMES FROM ELEMENT 9. THIS ALLOWS GPIO INPUTS TO BE INDIRECTLY CONNECTED TO ELEMENTS IN BLOCK 2 AND BLOCK 3.

Figure 25. PLA Element: Block 2 and Block 3

In total, 28 GPIO pins are available on each ADuCM320 for the PLA. These include 14 input pins and 14 output pins, which must be configured in the GPxCON register as PLA pins before using the PLA.

PLA OPERATION

The PLA is configured via a set of user MMRs. The output(s) of the PLA can be routed to the internal interrupt system, to the PLA_DOUTx MMRs, or to any of the 14 PLA output pins.

The GPIO inputs to the PLA are always connected to their corresponding elements regardless of the setting in GPxCON. This means that a pin could be used as both an output and an input to the PLA at the same time.

A PLA block can have several clock sources for its output flip-flops, or the flip-flops can be individually bypassed. All output flip-flops in the same block that are not bypassed share the same clock source. The configuration of the clock sources can be found in the PLA clock select register (PLA_CLK).

Each PLA element in a block can be connected to other elements in the same block by configuring the output of Mux 0 and Mux 1. The configuration of these two multiplexer can be found in the PLA_ELEMn configuration register. A complete list of the possible connections is given in Table 219 and Table 220.

The four blocks can be interconnected as follows:

- Output of Element 7 (Block 0 Element 7) can be fed back to the Input 0 of Mux 0 of Element 8 (Block 1 Element 0).
- Output of Element 15 (Block 1 Element 7) can be fed back to Input 0 of Mux 0 of Element 16 (Block 2 Element 0).
- Output of Element 23 (Block 2 Element 7) can be fed back to the Input 0 of Mux 0 of Element 24 (Block 3 Element 0).
- Output of Element 31 (Block 3 Element 7) can be fed back to Input 0 of Mux 0 of Element 0 (Block 0 Element 0).

See Figure 26 for more information.

There are four interrupts available for the PLA. These can be configured to trigger on the output of any element using the PLA_IRQ0 and PLA_IRQ1 registers. The interrupts are active high; therefore, the interrupts continue to be triggered until the output of the element goes low or until the IRQ is disabled. If an active low interrupt is required, an extra element must be configured as an inverter and then the interrupt must be configured to monitor the output of this new element. If an edge triggered interrupt is required, two extra elements must be used and configured as an edge detector (\overline{A} AND A).

GENERAL-PURPOSE TIMERS

GENERAL-PURPOSE TIMERS FEATURES

- Three identical general-purpose, 16-bit count-up/count-down timers
 - Timer 0, Timer 1, and Timer 2
- Clocked from five different clock sources
 - Peripheral clock (PCLK)
 - 80 MHz system clock (HCLK)
 - 32 kHz internal oscillator (LFOSC)
 - 16 MHz external crystal (HFXTAL) or internal 16 MHz oscillator (HFOSC), depending on the value in CLKCON0[11].
- Clock sources can be scaled down using a prescaler 16, 256, or 32,768. Additionally, two of the clocks can be scaled down using a prescaler of 4, and the other two clock sources can be used directly (prescaler of 1).
- Two modes
 - Free running
 - Periodic
- Capture events feature
 - Capability to capture 15 different events on each timer

GENERAL-PURPOSE TIMERS BLOCK DIAGRAM

NOTES
1. 16MHz EXTERNAL CRYSTAL (HFXTAL) OR INTERNAL 16MHz OSCILLATOR (HFOSC), DEPENDING ON THE VALUE IN CLKCON0[11].

11176-029

Figure 27. General-Purpose Timers Block Diagram

GENERAL-PURPOSE TIMERS OVERVIEW

Timer 0, Timer 1, and Timer 2 are three identical general-purpose, 16-bit count-up/count-down timers. They can be clocked from five different clock sources:

- PCLK
- HCLK
- 32 kHz internal oscillator (LFOSC)
- 16 MHz external crystal (HFXTAL) or internal 16 MHz oscillator (HFOSC), depending on the value in CLKCON0[11].

The clock sources can be scaled down using a prescaler of 1, 4, 16, 256, or 32,768.

The timers can be either free running or periodic.

- In free running mode, the counter decrements from full scale to zero scale or increments from zero scale to full scale and then restarts.
- In periodic mode, the counter decrements or increments from the value in the load register (TxLD MMR, where x is 0 for Timer 0, 1 for Timer 1, and 2 for Timer 2) until zero scale or full scale is reached and then restarts at the value stored in the load register.

The value of a counter can be read at any time by accessing its value register (TxVAL).

The TxCON register selects the timer mode, configures the clock source, selects count-up/count-down, starts the counter, and controls the event capture function.

An interrupt signal is generated each time the value of the counter reaches 0 when counting down, or each time the counter value reaches the maximum value when counting up. An IRQ can be cleared by writing 1 to the time clear interrupt register of that particular timer (TxCLRI).

In addition, Timer 0, Timer 1, and Timer 2 have a capture register (TxCAP) that is triggered by a selected IRQ source initial assertion. When triggered, the current timer value is copied to TxCAP, and the timer continues to run. This feature can be used to determine the assertion of an event with increased accuracy.

GENERAL-PURPOSE TIMERS OPERATION

Free Running Mode

In free running mode, the timer is started by setting the enable bit (TxCON[4]) to 1 and the MOD bit (TxCON[3]) to 0. The timer increments from zero scale/full scale to full scale/zero scale if counting up/down. Full scale is $2^{16} - 1$ or 0xFFFF in binary format. Upon reaching full scale (or zero scale), a timeout interrupt occurs and TxSTA[0] is set. To clear the timer interrupt, user code must write 1 to TxCLRI[0]. If TxCON[7] is set, the timer keeps counting and reloads when the TxCLRI register is written.

Periodic Mode

In periodic mode, the initial TxLD value should be loaded before starting the timer by setting the enable bit (TxCON[4]) to 1. The timer value either increments from the value in TxLD to full scale or decrements from the value in TxLD to zero scale, depending on the TxCON[2] settings (count up/down). Upon reaching full scale or zero scale, the timer generates an interrupt. The TxLD is reloaded into TxVAL, and the timer continues counting up or down. The timer should be disabled prior to changing the TxCON or TxLD register. If the TxLD register is changed while the timer is being loaded, undefined results may occur. By default, the counter is reloaded automatically when generating the interrupt signal. If TxCON[7] is set to 1, the counter is also reloaded when user code writes TxCLRI. This allows user changes to the TxLD to take effect immediately instead of waiting until the next timeout.

The timer interval is calculated as follows:

If the timer is set to count down, then

$$\text{Interval} = (\text{TxLD} \times \text{Prescaler}) / \text{Source Clock}$$

For example, if TxLD = 0x100, prescaler = 4, and clock source = UCLK, the interval is 12.8 μ s (where UCLK = 80 MHz).

If the timer is set to count up, then

$$\text{Interval} = ((\text{Full Scale} - \text{TxLD}) \times \text{Prescaler}) / \text{Source Clock}$$

Asynchronous Clock Source

Timers are started by setting the enable bit (TxCON[4]) to 1 in the control register of the corresponding timer.

However, when the timer clock source is HFXTAL or LFOSC, some precautions must be taken:

- The control register (TxCON) should not be written if TxSTA[6] is set. Therefore, TxSTA should be read prior to configuring the control register (TxCON). When TxSTA[6] is cleared, the register can be modified. This ensures that synchronizing the timer control between the processor and timer clock domains is complete. TxSTA[6] is the timer busy status bit.
- After clearing the interrupt in TxCLRI, it must be ensured that the register write has fully completed before returning from the interrupt handler. Use the data synchronization barrier (DSB) instruction if necessary and check that TxSTA[7] = 0.

```
__asm void asmDSB()
{
  nop
  DSB
  BX LR
}
```

- The value of a counter can be read at any time by accessing its value register (TxVAL). In an asynchronous configuration, TxVAL should always be read twice. If the two readings are different, it should be read a third time to determine the correct value.

TxSTA should be read prior to writing to any timer register after setting or clearing the enable bit. When TxSTA[7] is cleared, registers can be modified. This ensures that the timer has completed synchronization between the processor and timer clock domains. The typical synchronization time is two timer clock periods.

The TxCON register enables the counter, selects the mode, selects the prescale value, and controls the event capture function.

Capture Event Function

There are several interrupt events that can be captured by the general-purpose timers. These events are shown in Table 232. Any one of the events associated with a general-purpose timer can cause a capture of the 16-bit TxVAL register into the 16-bit TxCAP register. TxCON has a 4-bit field that can be used to select which event to capture.

When the selected interrupt event occurs, the TxVAL register is copied into the TxCAP register. TxSTA[1] is set, indicating that a capture event is pending. The bit is cleared by writing 1 to TxCLR[1]. The TxCAP register also holds its value and cannot be overwritten until a 1 is written to TxCLR[1].

Table 232. Capture Event Function

Event Select Bits (TxCON.EVENT) TxCON[11:8]	T0 Capture Source	T1 Capture Source	T2 Capture Source

REGISTER DETAILS: GENERAL-PURPOSE TIMER 0**16-Bit Load Value Register**

Address: 0x40000000, Reset: 0x0000, Name: TOLD

Table 234. Bit Descriptions for TOLD

Bits	Bit Name	Description	Reset	Access
[15:0]	LOAD	Load value. The Up/Down counter is periodically loaded with this value if periodic mode is selected (T0CON[3]=1). LOAD writes during Up/Down counter timeout events are delayed until the event has passed.	0x0	RW

16-Bit Timer Value Register

Address: 0x40000004, Reset: 0x0000, Name: T0VAL

Table 235. Bit Descriptions for T0VAL

Bits	Bit Name	Description	Reset	Access
[15:0]	VAL	Current count. Reflects the current Up/Down counter value. Value delayed two PCLK cycles due to clock synchronizers.	0x0	R

Control Register

Address: 0x40000008, Reset: 0x000A, Name: T0CON

Table 236. Bit Descriptions for T0CON

Bits	Bit Name	Description	Reset	Access
[15:13]	RESERVED		0x0	R
12	EVENTEN	Event select. Used to enable and disabling the capture of events. Used in conjunction with the EVENT select range: when a selected event occurs the current value of the Up/Down counter is captured in T0CAP. 0: Events will not be captured 1: Events will be captured	0x0	RW
[11:8]	EVENT	Event select range. Timer event select range (0 - 15).	0x0	RW
7	RLD	Reload control. RLD is only used for periodic mode; this bit allows the user to select whether the Up/Down counter should be reset only on a timeout event or also when T0CLR1[0] is set. 1: Resets the up/down counter when T0CLR1[0] is set 0: Up/Down counter is only reset on a timeout event	0x0	RW
[6:5]	CLK	Clock select. Used to select a timer clock from the four available clock sources. 00: PCLK. 01: HCLK. 10: LFOSC. 32 KHz OSC 11: HFXTAL. 16 MHz OSC or XTAL, Dependent on the value in CLKCON0[11]	0x0	RW

Bits	Bit Name	Description	Reset	Access
4	ENABLE	Timer enable. Used to enable and disable the timer. Clearing this bit resets the timer, including the T0VAL register. 0: DIS. Timer is disabled (default) 1: EN. Timer is enabled	0x0	RW
3	MOD	Timer mode. This bit is used to control whether the timer runs in periodic or free running mode. In periodic mode the up/down counter starts at the defined LOAD value (T0LD); in free running mode the up/down counter starts at 0x0000 or 0xFFFF depending on whether the timer is counting up or down. 0: FREERUN. Timer runs in free running mode 1: PERIODIC. Timer runs in periodic mode (default)	0x1	RW
2	UP	Count up. Used to control whether the timer increments (counts up) or decrements (counts down) the Up/Down counter. 0: DIS. Timer is set to count down (default) 1: EN. Timer is set to count up	0x0	RW
[1:0]	PRE	Prescaler. Controls the prescaler division factor applied to the timer's selected clock. If CLK Source 0 (PCLK) or CLK Source 1 (HCLK) is selected, then Prescaler value 0 means divide by 4, else it means divide by 1. 00: source_clock / [1 or 4] 01: source_clock / 16 10: source_clock / 256 11: source_clock / 32,768	0x2	RW

Clear Interrupt Register

Address: 0x4000000C, Reset: 0x0000, Name: T0CLRI

Table 237. Bit Descriptions for T0CLRI

Bits	Bit Name	Description	Reset	Access
[15:2]	RESERVED		0x0	R
1	CAP	Clear captured event interrupt. This bit is used to clear a capture event interrupt. 0: No effect 1: Clear the capture event interrupt	0x0	W1C
0	TMOUT	Clear timeout interrupt. This bit is used to clear a timeout interrupt. 0: No effect 1: Clears the timeout interrupt	0x0	W1C

Capture Register

Address: 0x40000010, Reset: 0x0000, Name: T0CAP

Table 238. Bit Descriptions for T0CAP

Bits	Bit Name	Description	Reset	Access
[15:0]	CAP	16-bit captured value. T0CAP will hold its value until T0CLRI[1] is set by user code. T0CAP will not be over written even if another event occurs without writing to the T0CLRI[1].	0x0	R

Status Register

Address: 0x4000001C, Reset: 0x0000, Name: T0STA

Table 239. Bit Descriptions for T0STA

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED		0x0	R
7	PDOK	TOCLR synchronization. This bit is set automatically when the user sets TOCLR[0]=1. It is cleared automatically when the clear interrupt request has crossed clock domains and taken effect in the timer clock domain. 0: CLR. The interrupt is cleared in the timer clock domain 1: SET. TOCLR[0] is being updated in the timer clock domain	0x0	R
6	BUSY	Timer Busy. This bit informs the user that a write to TOCON is still crossing into the timer clock domain. This bit should be checked after writing TOCON and further writes should be suppressed until this bit is cleared. 0: CLR. Timer ready to receive commands to TOCON 1: SET. Timer not ready to receive commands to TOCON	0x0	R

WATCHDOG TIMER

WATCHDOG TIMER FEATURES

16-bit count-down timer, which can be used to recover from an invalid software state.

Clocked by the 32 kHz internal oscillator (LFOSC) with a programmable prescaler (1, 16, 256, or 4096).

WATCHDOG TIMER BLOCK DIAGRAM

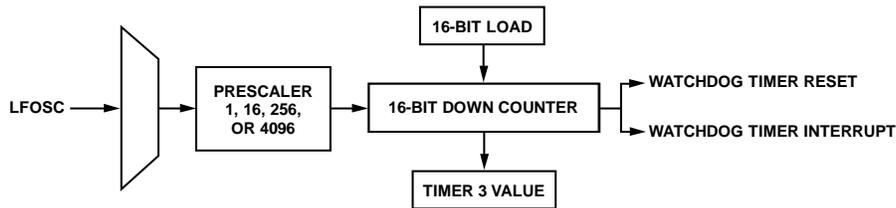

Figure 28. Watchdog Timer Block Diagram

11176-032

WATCHDOG TIMER OVERVIEW

The watchdog timer (Timer 3) is used to recover from an invalid software state. When enabled, this timer requires periodic servicing to prevent it from forcing a reset of the device. For debug purposes, the timer can be configured to generate an interrupt instead of a reset.

The watchdog timer is clocked by the internal 32.768 kHz oscillator, LFOSC. It is clocked at all times except during a reset.

The watchdog timer is a 16-bit count-down timer with a programmable prescaler. The prescaler is selectable and can divide LFOSC by a factor of 1, 16, 256, or 4096.

WATCHDOG TIMER OPERATION

The watchdog timer is enabled by default after a reset.

User code should disable the watchdog timer at the start of user code when debugging or if the watchdog timer is not required.

```
T3CON = 0x00; // Disable watchdog timer
```

Enabling the watchdog timer (set T3CON[5] = 1) also write protects T3CON and T3LD.

This means that after kernel execution, user code can disable the timer and then reconfigure it with T3CON[5] = 1 only once. Then T3CON and T3LD are write protected. T3STA[4] indicates if the timer configuration has been locked. Only a reset clears T3CON[5], unlocking T3CON and T3LD, and allows reconfiguration of the timer.

If T3CON is not modified, user code can change T3LD at any time. If T3CON[5] is cleared to 0, the timer is disabled. Settings can be modified, and the timer can be reenabled.

When the watchdog timer is used in interrupt mode, T3STA[0], the WDT interrupt bit, is set to 1 for only a very short period ($2 \times PCLK$). Therefore, T3STA[0] should not be used for polling purposes.

WAKE-UP TIMER

WAKE-UP TIMER FEATURES

- 32-bit counter (count down or count up)
- Three clock sources with programmable prescaler (1, 16, 256, or 32,768)
 - Peripheral clock (PCLK)
 - 32 kHz internal oscillator (LFOSC)
 - External clock applied on Pin P1.0 (ECLKIN)
- Four compare points, one automatic increment

WAKE-UP TIMER BLOCK DIAGRAM

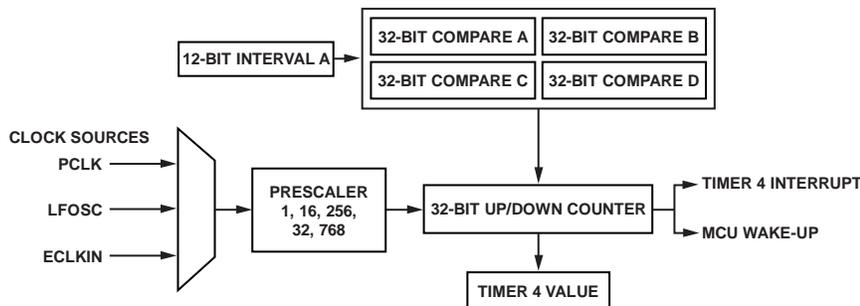

Figure 29. Wake-Up Timer Block Diagram

11176-030

WAKE-UP TIMER OVERVIEW

The wake-up timer (Timer 4) block consists of a 32-bit counter clocked from one of three different sources: the system clock (PCLK), the internal oscillator (LFOSC), or an external clock applied on Pin P1.0 (ECLKIN). The selected clock source can be scaled down using a prescaler of 1, 16, 256, or 32,768. The wake-up timer continues to run independent of the clock source used when the PCLK clock is disabled.

The timer can be used in free running or periodic mode. In free running mode, the timer counts from 0x00000000 to 0xFFFFFFFF and then restarts at 0x00000000. In periodic mode, the timer counts from 0x00000000 to T4WUFD (T4WUFD0 and T4WUFD1).

In addition, the wake-up timer has four specific time fields to compare with the wake-up counter: T4WUFA, T4WUFB, T4WUFC, and T4WUFD. All four wake-up compare points can generate interrupts or wake-up signals. When the timer is in free running mode, T4WUFA, T4WUFB, T4WUFC, and T4WUFD must be reconfigured in software to generate a periodic interrupt.

WAKE-UP TIMER OPERATION

The wake-up timer comparator registers must be configured before starting the timer. The timer is started by writing the control enable bit (T4CON[7]). The timer increments until the value reaches full scale in free running mode or when T4WUFD matches the wake-up value, T4VAL.

The wake-up timer is a 32-bit timer. Its current value is stored in two 16-bit registers: T4VAL1 stores the upper 16 bits, and T4VAL0 stores the lower 16 bits.

When T4VAL0 is read, T4VAL1 is frozen at its current value until it is subsequently read. The control bit FREEZE (T4CON[3]) must be set to freeze the T4VAL register between the lower and upper reads.

Clock Selection

Clock selection is made by setting T4CON[10:9].

If PCLK is selected (T4CON[10:9] = 00), configuring T4CON[1:0] = 00 results in a prescaler of 4.

Synchronization to the LFOSC clock domain is done automatically by hardware, and precautions concerning asynchronous clocks as described in Timer 0, Timer 1, and Timer 2 do not apply.

Compare Field Registers

Hardware Updated Field

T4INC is a 12-bit interval register that is used to update the compare value in T4WUF_{Ax} by hardware. When a new value is written in T4INC, Bits[16:5] of the internal 32-bit compare register (T4WUF_{Ax}) are loaded with the new T4INC value. If the new compare value is less than the T4WUFD value in periodic mode or less than 0xFFFFFFFF in free running mode, this 32-bit compare register is automatically incremented with the contents of T4INC (shifted by five) each time the wake-up counter reaches the value in this compare register. If the new compare value is greater than these limits, it is recalculated as follows.

In free running mode, the new value is

$$T4WUFA = Old\ T4WUFA + (32 \times T4INC) - 0xFFFFFFFF$$

In periodic mode, the new value is

$$T4WUFA = Old\ T4WUFA + (32 \times T4INC) - T4WUFD$$

The maximum programmable interval is just above 4 seconds.

T4INC is compared with Bits[16:5] of the timer value. Because it is shifted left by five bits, its value must be multiplied by 32 to obtain the compare value.

With the default value of 0xC8 (where for calculation purposes 0xC8 = 200 in decimal), a prescaler = 1, and 32 kHz clock selected,

$$Interval = ((200 \times 32) + 1) \times 1/32,768 = 195.3155\ ms$$

To modify the interval value, the timer must be stopped so that the interval register can be loaded in the compare register if T4CON[11] = 0.

To modify the interval value, set STOPINC (T4CON[11] = 1) while the timer is running.

The new T4INC value takes effect after the next Wake-Up Field A interrupt. If the user is writing to this register while the timer is enabled, the STOPINC bit should be set before writing to it, and then STOPINC should be cleared after the update.

Software Updated Field

T4WUFB, T4WUFC, and T4WUFD are 32-bit values programmed by the user in the T4WUF_{x0} and T4WUF_{x1} registers (x = B, C, or D). T4WUFD contains the load value when the wake-up timer is configured in periodic mode.

The T4WUF_{Bx} and T4WUF_{Cx} registers can be written to at any time, but the corresponding interrupt enable (T4IEN[1] or T4IEN[2]) must be disabled. After the register is updated, the interrupt can be reenabled.

In periodic mode, the T4WUFD_x registers can be written to only when the timer is disabled. In free running mode, the T4WUFD_x registers can be written to while the timer is running. Before doing so, the corresponding interrupt enable (T4IEN[3]) must be disabled. After the register is updated, the interrupt can be reenabled.

In free running mode, T4WUFB, T4WUFC, and T4WUFD can be written to at any time, but the corresponding interrupt enable in the T4IEN register must be disabled. After the register is updated, the interrupt can be reenabled. In periodic mode, this is only applicable to T4WUFB and T4WUFC.

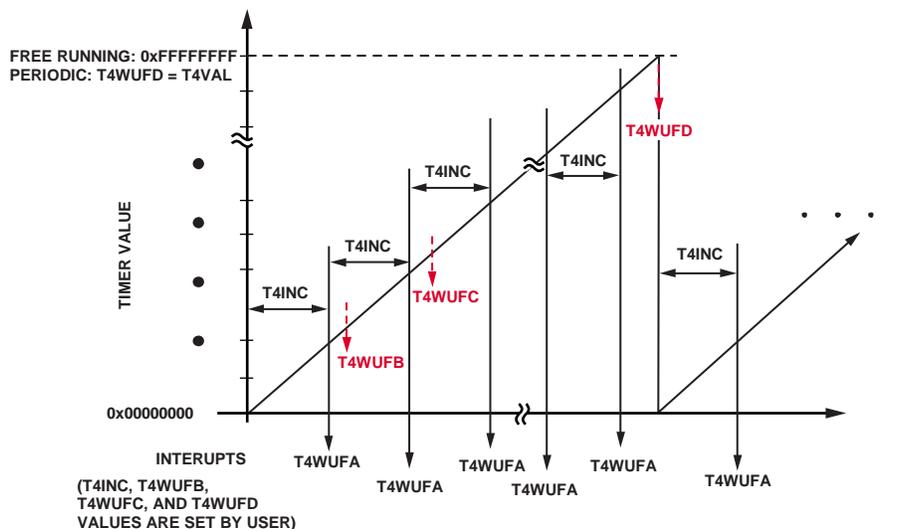

Figure 30. Wake-Up Timer Fields Action

Interrupts/Wake-Up Signals

An interrupt is generated when the counter value corresponds to any of the compare points or full scale in free running mode. The timer continues counting or is reset to 0.

The wake-up timer generates five maskable interrupts. They are enabled in the T4IEN register. Interrupts can be cleared by setting the corresponding bit in the T4CLR register.

Note that it takes two 32 kHz clock cycles for the interrupt clear to take effect when the 32 kHz internal oscillator is used.

Ensure that the register write has fully completed before returning from the interrupt handler. Use the data synchronization barrier (DSB) instruction if necessary. The following is a code example showing how to implement the DSB ARM Cortex-M3 instruction in a C program.

```
void Ext_Int4_Handler ()
{
    EiClr(EXTINT4);
    __DSB();
}
```

During that time, the part should not be placed in any of the power-down modes. IRQCRY (T4STA[6]) indicates when the device can be placed in power-down mode.

The timer is stopped and reset when clearing the timer enable bit in the T4CON register (T4CON[7]).

PWM

PWM FEATURES

- 8-channel PWM interface

PWM OVERVIEW

The ADuCM320 integrates an 8-channel PWM interface. Eight channels are grouped as three pairs (0 to 3). The first two pairs of PWM outputs (PWM0, PWM1, PWM2, and PWM3) can be configured to drive an H-bridge. Upon power-up, the PWM outputs default to H-bridge mode. In the standard mode, users have control over the period of each pair of outputs and over the duty cycle of each individual output. The PWM trip interrupt can be cleared by writing 1 to PWMICLR[4]. When using the PWM trip interrupt, the PWM interrupt should be cleared before exiting the ISR. This prevents the generation of multiple interrupts. PWM0 to PWM6 are available on external pins.

Table 276. PWM Channel Grouping

Port Name	Description	PWM Mode Available
PWM0	High-side PWM output for Pair 0	H-bridge and standard
PWM1	Low-side PWM output for Pair 0	H-bridge and standard
PWM2	High-side PWM output for Pair 1	H-bridge and standard
PWM3	Low-side PWM output for Pair 1	H-bridge and standard
PWM4	High-side PWM output for Pair 2	Standard
PWM5	Low-side PWM output for Pair 2	Standard
PWM6	High-side PWM output for Pair 3	Standard
PWM7	Low-side PWM output for Pair 3	Standard

PWM OPERATION

In all modes, the PWMxCOMx MMRs control the point at which the PWM output changes state. The PWM clock is selectable via PWMCON0 with one of the following values: UCLK divided by 2, 4, 8, 16, 32, 64, 128, or 256.

The length of the PWM period is defined by PWMxLEN. Each pair has an associated counter.

The PWM waveforms are set by the count value of the 16-bit timer and the compare register contents.

The low-side waveform, PWM1, goes high when the timer count reaches PWM0LEN, and it goes low when the timer count reaches the value held in PWM0COM2 or when the high-side waveform PWM0 goes low.

The high-side waveform, PWM0, goes high when the timer count reaches the value held in PWM0COM0, and it goes low when the timer count reaches the value held in PWM0COM1.

Note that the high-side PWM output for each channel must have a high duration period that is greater than or equal to the high period duration of the low-side output. For example, the high period for PWM0 must be equal to or greater than the high period of PWM1.

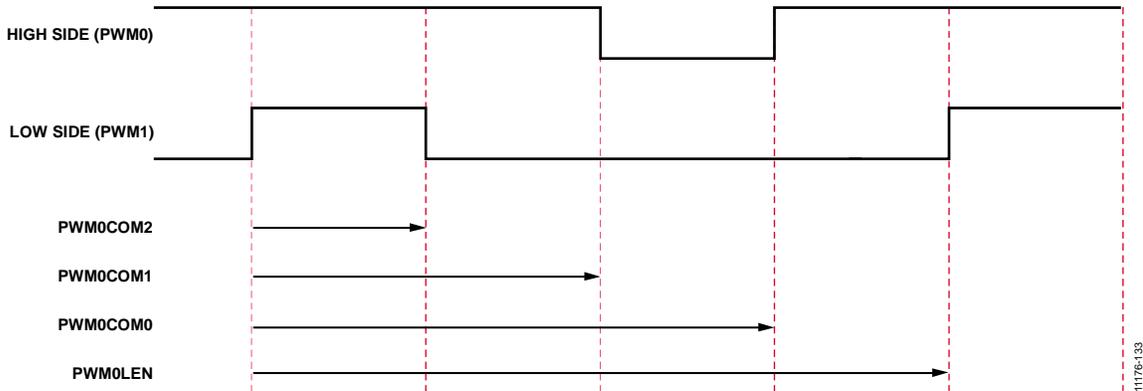

Figure 31. Waveform of PWM Channel Pair in Standard Mode

Table 277 lists equations for the period and duration for both the outputs of a PWM channel. Note that

- $t_{UCLK/DIV}$ is the PWM clock frequency selected by CLKCON1[2:0] and CLKSYS DIV[0].
- $N_{PRESCALE}$ = prescaler value as determined by PWMCON0[8:6].

Table 277. PWM Equations

PWM	Period	Low Duration
Low Side (PWM1)	$t_{UCLK/DIV} \times (PWM0LEN + 1) \times N_{PRESCALE}$	If (PWMCOM2 < PWMCOM1), then $t_{UCLK/DIV} \times (PWM0LEN - PWM0COM2) \times N_{PRESCALE}$ Else $t_{UCLK} \times (PWM0LEN - PWM0COM1) \times N_{PRESCALE}$
High Side (PWM0)	$t_{UCLK/DIV} \times (PWM0LEN + 1) \times N_{PRESCALE}$	$t_{UCLK/DIV} \times (PWM0COM0 - PWM0COM1) \times N_{PRESCALE}$

Standard Mode

In standard mode, each pair is individually controlled by a selection of registers, as shown in Table 278.

Table 278. Compare Register Descriptions in Standard Mode (Base Address: 0x40024000)

Name	Offset	Description
PWM0COM0	0x010	PWM0 output goes high when the PWM timer reaches the count value stored in this register.
PWM0COM1	0x014	PWM0 output goes low when the PWM timer reaches the count value stored in this register.
PWM0COM2	0x018	PWM1 output goes low when the PWM timer reaches the count value stored in this register.
PWM0LEN	0x01C	PWM1 output goes high when the PWM timer reaches the count value stored in this register.
PWM1COM0	0x020	PWM2 output goes high when the PWM timer reaches the count value stored in this register.
PWM1COM1	0x024	PWM2 output goes low when the PWM timer reaches the count value stored in this register.
PWM1COM2	0x028	PWM3 output goes low when the PWM timer reaches the count value stored in this register.
PWM1LEN	0x02C	PWM3 output goes high when the PWM timer reaches the count value stored in this register.
PWM2COM0	0x030	PWM4 output goes high when the PWM timer reaches the count value stored in this register.
PWM2COM1	0x034	PWM4 output goes low when the PWM timer reaches the count value stored in this register.
PWM2COM2	0x038	PWM5 output goes low when the PWM timer reaches the count value stored in this register.
PWM2LEN	0x03C	PWM5 output goes high when the PWM timer reaches the count value stored in this register.
PWM3COM0	0x040	PWM6 output goes high when the PWM timer reaches the count value stored in this register.
PWM3COM1	0x044	PWM6 output goes low when the PWM timer reaches the count value stored in this register.
PWM3COM2	0x048	PWM7 output goes low when the PWM timer reaches the count value stored in this register.
PWM3LEN	0x04C	PWM7 output goes high when the PWM timer reaches the count value stored in this register.

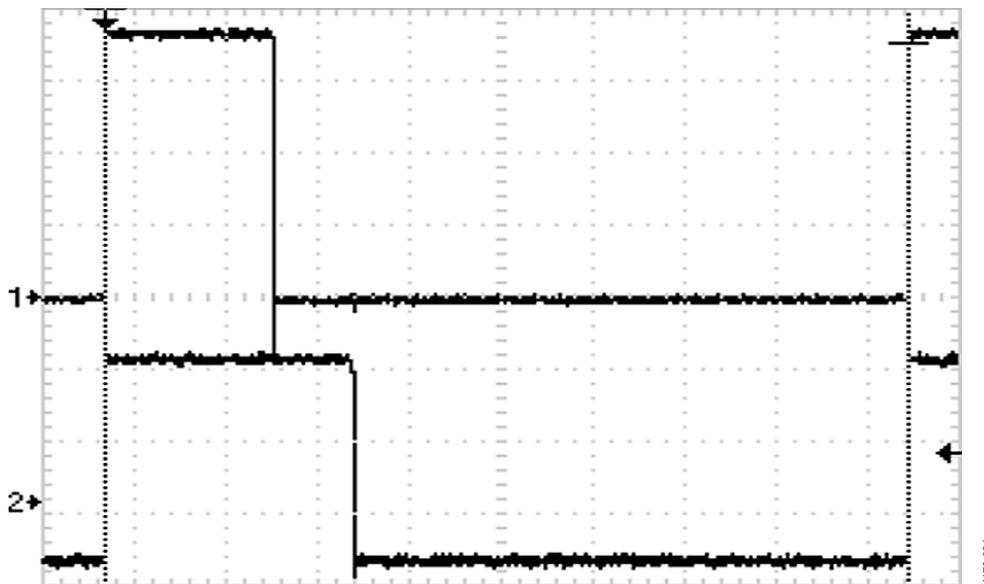

Figure 32. PWM Output on PWM0 and PWM1 Pins (PWM0 is Channel 2)

1176-034

H-Bridge Mode

In H-bridge mode, the two pairs of frequency and duty cycle are controlled by PWM0COM0, PWM0COM1, and PWM0LEN. For H-bridge mode, HMODE = 1 (PWMCON0[1] = 1). The HMODE bit also works with PWMCON0[5:2] for H-bridge mode. Note that only PWM0 to PWM3 participate in H-bridge mode; other outputs (PWM4 and PWM5) do not and continue to generate standard mode output.

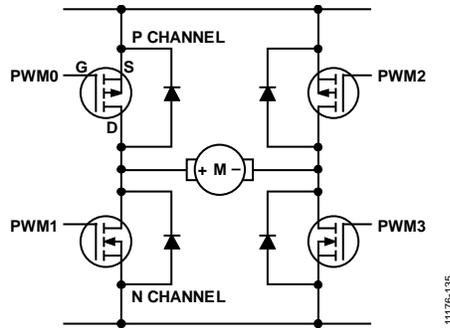

Figure 33. Example H-Bridge Configuration

Table 279. PWM Output in H-Bridge Mode

PWM Control Bits				PWM Outputs ¹				
ENA PWMCON0[9]	POINV PWMCON0[5]	HOFF PWMCON0[4]	DIR PWMCON0[2]	PWM0	PWM1	PWM2	PWM3	State of Motor
0	X	0	X	1 (disable)	1 (enable)	1	1	Brake
X	X	1	X	1 (disable)	0 (disable)	1	0	Free run
1	0	0	0	0 (enable)	0 (disable)	HS	LS	Move controlled by LS on PWM2
1	0	0	1	HS	LS	0	0	Move controlled by HS on PWM0
1	1	0	0	\overline{LS}	\overline{HS}	1	1	Move controlled by LS on PWM0
1	1	0	1	1 (disable)	1 (enable)	\overline{LS}	\overline{HS}	Move controlled by \overline{HS} on PWM2

¹ HS = high side, LS = low side, \overline{HS} = inverse of high side, \overline{LS} = inverse of low side, as programmed in PWM0 registers.

PWM INTERRUPT GENERATION

PWM Trip Function Interrupt

When the PWM trip function is enabled (TRIPEN, PWMCON1[6]) and the PWM trip input signal goes low (falling edge), the PWM peripheral disables itself (PWMCON0[0] = 0). It also generates the PWM trip interrupt. The interrupt is cleared by setting PWMCLRI[4].

PWM Output Pairs Interrupts

In standard mode, each PWM pair has a dedicated interrupt: IRQPWM0, IRQPWM1, IRQPWM2, IRQPWM3.

In H-bridge mode, only IRQPWM0 is available.

When the interrupt generation is enabled (PWMCON0[10]) and the counter value for Pair 0 changes from PWM0LEN to 0, it also generates the IRQPWM0 interrupt. The interrupt is cleared by setting PWMCLRI[0].

When the interrupt generation is enabled (PWMCON0[10]) and the counter value for Pair 1 changes from PWM1LEN to 0, it also generates the IRQPWM1 interrupt. The interrupt is cleared by setting PWMCLRI[1].

When the interrupt generation is enabled (PWMCON0[10]) and the counter value for Pair 2 changes from PWM2LEN to 0, it also generates the IRQPWM2 interrupt. The interrupt is cleared by setting PWMCLRI[2].

When the interrupt generation is enabled (PWMCON0[10]) and the counter value for Pair 3 changes from PWM3LEN to 0, it also generates the IRQPWM3 interrupt. The interrupt is cleared by setting PWMCLRI[3].

REGISTER SUMMARY: PWM

Table 280. PWM Register Summary

Address	Name	Description	Reset	RW

MDIO

MDIO FEATURES

The MDIO interface hardware can receive complete MDIO frames without software intervention. The MDIO interface hardware can also transmit complete MDIO frames without software intervention as long as the data to be sent is provided before receiving the turnaround bits (TA) of the read or PostReadIncAdd frame. To assist in using and supplying the relevant data, interrupts are generated at the end of every complete frame. If the PHYADR or DEVADD received does not match the expected values, then the frame will not be acted upon. Interrupts are also generated after every valid PHYADR and DEVADD to permit more sophisticated control within frames.

MDIO OVERVIEW

This MDIO interface is designed for compliance with CFP management interface architecture (as per Draft CFP MSA Management Interface Specification Version 2.0 r07, June 30, 2011), as shown in Figure 34. This architecture includes an MDIO hardware interface to handle the serial communications. The transfer of data between this CFP MDIO interface and the MDIO defined memory blocks is done via software.

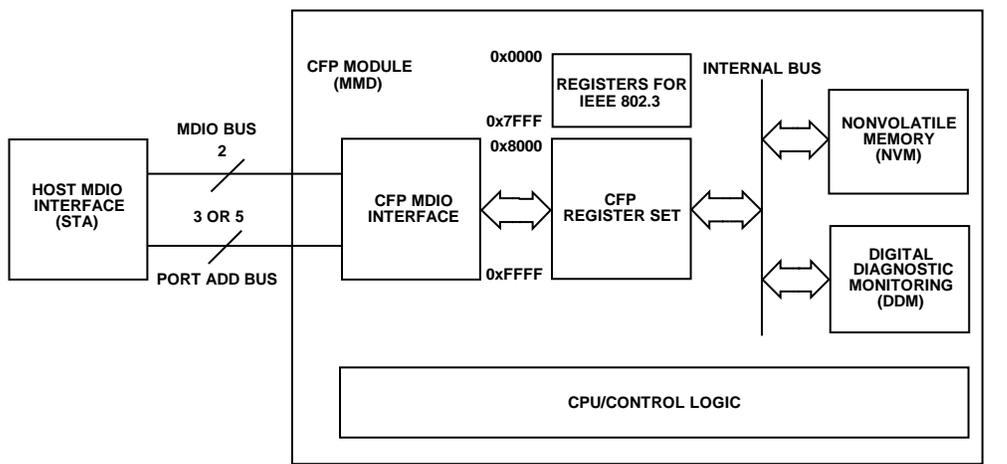

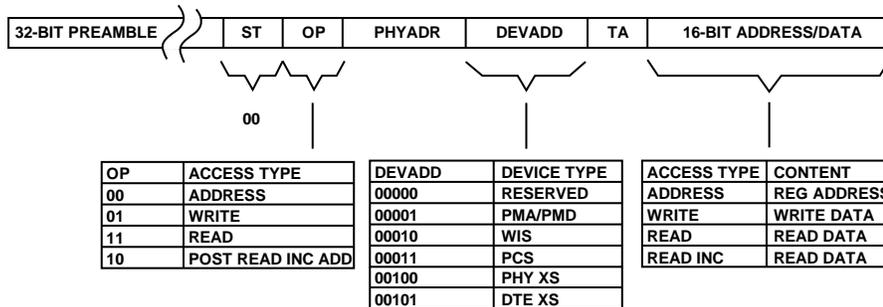

Figure 34. CFP management interface architecture

MDIO OPERATION

MDIO Frame Structure

The MDIO interface uses the communication data frame structure defined in IEEE 802.3 Clause 45. The frame structure is shown in Figure 35. Each frame can be either an address frame or a data frame. The total bit length of each frame is 64, consisting of 32 bits preamble, and the frame command body. The command body consists of six portions, as illustrated in Figure 35. More information about the various frame types is provided in Table 300. All values are transmitted MSB first.

ST = START BITS (2 BITS),
 OP = OPERATION CODE (2 BITS),
 PHYADR = PHYSICAL PORT ADDRESS (5 BITS),
 DEVADD = MDIO DEVICE ADDRESS (OR CALLED DEVICE TYPE, 5 BITS),
 TA = TURNAROUND BITS (2 BITS),
 16-BIT ADDRESS/DATA IS THE PAYLOAD.

Figure 35. MDIO Frame Structure

Table 300. Frame Details for Different Frame Types¹

Frame	Idle	Management Frame Fields							Idle
		PRE	ST	OP	PHYADR	DEVADD	TA	Address/Data	
Write Address	z	1...1	00	00	aaaaa	aaaaa	10	aaaaaaaaaaaaaaaa	z
Write Data	z	1...1	00	01	aaaaa	aaaaa	10	ddddddddddddddd	z
Read Data	z	1...1	00	11	aaaaa	aaaaa	z0	ddddddddddddddd	z
PostReadIncAdd	z	1...1	00	10	aaaaa	aaaaa	z0	ddddddddddddddd	z

¹ During the idle condition, MDC and MDIO are not actively driven. During the second bit of TA and during the 16-bit data of the read and PostReadInc add frames, MDIO is driven by the MMD. At all other times, ADC and MDIO are driven by the STA bits.

IDLE (Idle Condition)

The idle condition for the MDIO is a high-impedance state.

PRE (Preamble)

At the beginning of each transaction, the STA (host) sends a sequence of at least 32 contiguous bits sent one bit at a time to the MDIO, with 32 corresponding clock cycles on MDC, to establish the start of a frame.

ST (Start of Frame)

After the PRE the ST (consisting of two zero bits) indicates the start of the frame information.

OP (Operation Code)

The OP specifies the action to be taken, as described in Table 301.

Table 301. Operation Code

OP	Descriptions
00	Set the address for a subsequent write or read frame.
01	Write to the previously set address.
11	Read from the previously set address.
10	Read from the previously set address. Then increment the address. Note that user code must increment the address in the MDADR register.

PHYADR (Physical Address)

This address is five bits, allowing 32 unique addresses. The PHYADR is set either by 5 pins or by software.

DEVAD (Device Address)

This address is five bits and selects the device type. In the CFP standard, only MDIO Device Address 1 is supported.

TA (Turnaround)

This time is used to change from being driven by the STA to being driven by the MMD as per Figure 35.

Address/Data

The address/data field is 16 bits.

Typical Usage Sequence

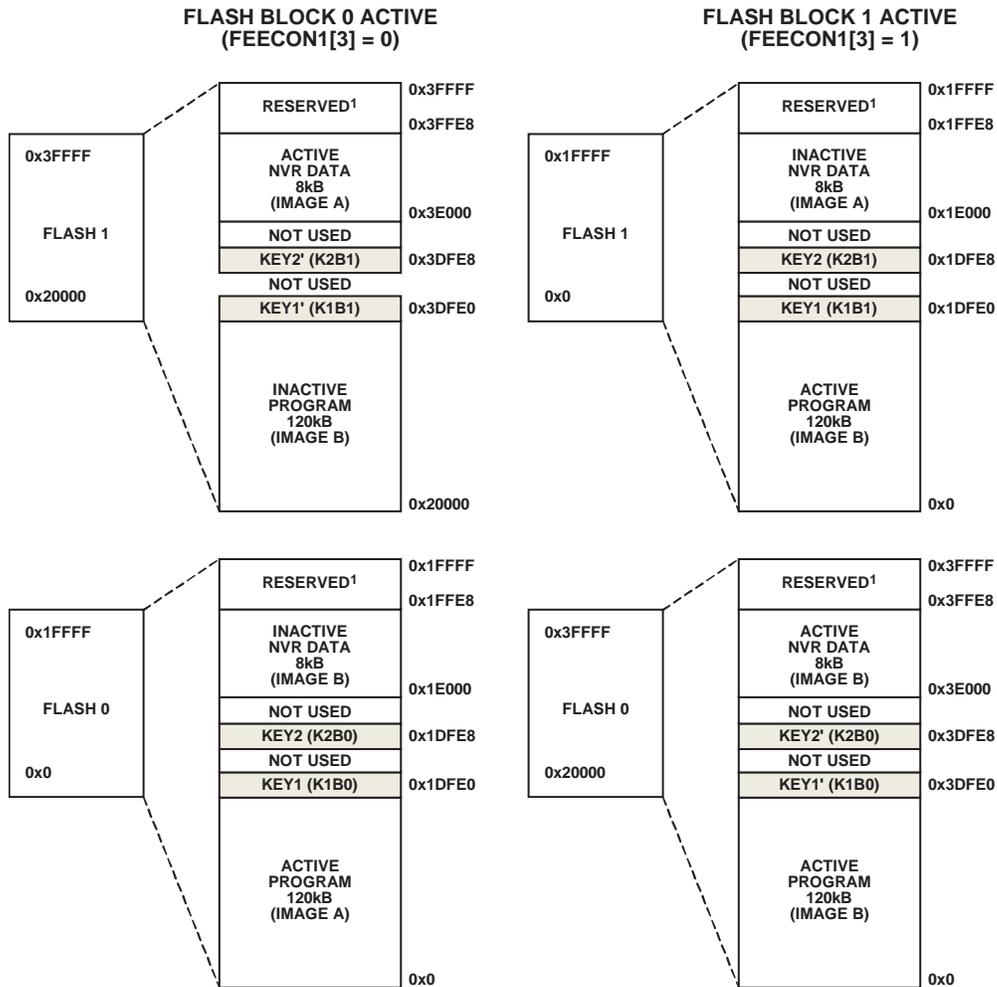

Most of the MDIO interface is implemented in hardware, thus requiring minimal software effort.

1. Enable the MDIO onto the physical pins by writing 0x0555 to GP3CON.
2. Set the frame parameters by means of MDPHY, MDCON, and MDPIN.
3. Set the interrupts with MDIEN plus the required system interrupt settings.
4. At this stage, the address and write frames can be received in MDRXD and MDADR, respectively.
5. Data must be placed in MDTXD in advance of the read or PostReadInc frame so that it can be automatically inserted for the frame.

No software intervention is required during any of the transmissions, although frame progress can be monitored with MDFRM during or upon completion of each frame. MDSTA should not be used to check frame progress because this MMR is autocleared and bits could be lost if read at an inappropriate time. If it is required to monitor frame progress, then the appropriate time to read MDSTA should be based on interrupts or by polling the MDIO bit in INTSETP0 in the interrupt system. MDSTA should be read only once per frame. MDIO must have the highest interrupt priority of all peripherals; otherwise, MDIO events will likely be lost.

BLOCK SWITCHING

For MDIO applications, the system memory is separated into two flash blocks as shown in Figure 36.

¹SEE THE FLASH CONTROLLER SECTION FOR MORE INFORMATION ABOUT RESERVED LOCATIONS.

11176-136

Figure 36. Memory Maps for MDIO Block Switching

Flash Block Partitioning

In the MDIO dual program image configuration, the Program Image A in Flash 0 and the NVR Data Block A in Flash 1 should be used together or, alternatively, the Program Image B in Flash 1 and the NVR Data Block B in Flash 0 should be used together. Because the data and code are in different flash blocks, the code can continue executing in the active program image while flash operations are performed on the associated NVR data flash block. Only one combination should be used at a time, which is known as the active combination. The other combination can be updated with new code if required, and by means of the block switching described, code can be made to execute from the new code. In the unswitched mode, Flash Block 0 is mapped from 0 to 0x1FFFF and Flash Block 1 is mapped from 0x20000 to 0x3FFFF. In the switched mode, Flash Block 1 is mapped from 0 to 0x1FFFF and Flash Block 0 is mapped from 0x20000 to 0x3FFFF. Code should be built to run in the address range 0 to 0x1FFFF and should only be run in this range. A mechanism is provided in the kernel to run from the appropriate flash block after any reset. This is described in the subsequent subsections of the MDIO section.

For a complete understanding, see Table 303, Figure 37, and Table 302 for additional information.

Program Image

The choice of which blocks are used is determined by the kernel and based on keys placed at the top of the two 120 kB program image blocks. There are six modes of operation:

- Debug mode
- Downloader mode (no valid code)
- Normal running from Program Image A (Flash 0)
- Trial run from Program Image A (Flash 0)
- Normal running from Program Image B (Flash 1)
- Trial run from Program Image B (Flash 1)

Each of these modes can be entered only via a reset. Every reset causes the kernel to run, and the kernel chooses the appropriate mode according to keys in the program images.

Each program image contains two keys.

For the active program image, Key1 at Address 0x1DFE0 has a numeric value that indicates the update number. The higher the Key1 value, the more recent the update.

Key2 at Address 0x1DFE8 is used to manage trial runs. A value of 0xFFFFFFFF (erased) indicates a new download. When trial run has passed, this must be indicated by changing the value to 0.

Key1' of the other program image is at 0x3DFE0. Key2' of the other program image is at 0x3DFE8.

The user program space CRCs can be stored at 0x1DFFC for Flash 0 and at 0x3DFFC for Flash 1. The CRC is not required as part of the block selection mechanism but should be included for increased robustness. The user code can check this CRC periodically.

Note that the keys are placed just below the 120 kB boundary, which is assumed to be the top of the program space. There is no technical reason why some code cannot be placed above this boundary or why some data cannot be placed below this boundary.

Debug Mode

If after a reset the kernel determines that the download pin (P2.3) is high, the kernel enters user code regardless of the keys. This mode is intended for debugging only.

Choosing the Active Block

After any reset, the kernel chooses the active program image.

Figure 37 is the flowchart for choosing the active program image.

Initially, the kernel assumes that the program image with the larger Key1 will be made active. If the associated Key2 is not 0, this code has not passed the trial run and should not yet be used. Instead, the kernel investigates using the other program image. If the Key2' of the other program image is 0, that program image is chosen. Based on these decisions, the kernel then sets the active program image and exits to user code. If neither program image has a valid Key2, the kernel enters its own download mode.

Trial Run Mode

After user code is entered, the code checks whether a trial run or a normal run should be performed. A trial run is indicated if the active Key1 is less than the other Key1'. In a trial run, the old code first checks that the new program image is functioning correctly. The trial run starts in the old program image and performs initial checks, such as CRCs and other checks that the user deems necessary, on the new program image. The trial run can then continue by switching to the new image using Bit 3 of MMR FEECON1. It is recommended that the code that performs the switching be at a fixed location in Flash Page0 and be the same in all revisions. The code following the switching point should include sufficient identical code so that the CPU pipeline plus the flash lookahead buffers contain the expected code after switching. The user must also clear the memory cache to prevent old code from executing after the switch.

The trial run should also copy all necessary data from the old NVR to the new NVR. After the new flash blocks are shown to be correct, the user code must write 0 to Key2' of the new flash block to mark the block as good. The user code can then initiate normal operation. Alternatively, a software reset can be issued, and then the device enters normal mode in the new program image.

A reset may occur during a trial run, for instance, due to power loss or during a watchdog event due to program hanging or a deliberate software reset. In this case, a trial run restarts in the old code, and then the trial run code decides how to proceed.

Normal Mode

The user code must check whether a trial run or a normal run should be performed. A normal run is indicated if the active Key1 is larger than the other Key1'. During normal operation, the MDIO master can send download information to the active user code so that new

code is written to the other program image. Such a download must also write the new Key1' with a value of one more than the active Key1. The new Key2' must be left erased as 0xFFs. After the download, the part must be reset to allow a trial run to occur.

Typical Sequence

A typical sequence is shown in Table 302.

On a new device, the initial code can be downloaded via SW JTAG if P2.3 is held high during a reset; otherwise, the kernel will enter its own downloader because there is no valid key. At the end of the download to Flash 0, Key1 is set to 1 and Key2 is set to 0.

After a reset, normal code is run from Flash 0 because its Key1 is greater than Key1' (0xFFs = -1) and its Key2 is 0. User code can receive MDIO frames instructing it to download code to Flash 1, which results in the new Key2' being erased and 2 being written to the new Key1'.

After a reset, the kernel activates Flash 0 for a trial run on the new code because Key2' of Flash 1 is 0xFFs. If the trial run passes, then the user code sets Key2 to 0 and issues a software reset.

After a reset, the kernel selects Flash 1 because its Key1 is still larger than the other Key1 and the active Key2 is 0. User code can receive MDIO frames instructing it to download code, including copying the NVR data block, to Flash 0, which results in Key2 being erased and 3 being written to Key1.

Changeover back to Flash 0 is then similar to the change to Flash 1.

Table 302. Example Block Switching Sequence

Number of Software Download	Key2 of Flash 0	Key1 of Flash 0	Key2 of Flash 1	Key1 of Flash 1	Status	Reset Required?
N/A	0xFFFFFFFF	0xFFFFFFFF	0xFFFFFFFF	0xFFFFFFFF	Initial startup	
1	0	1	0xFFFFFFFF	0xFFFFFFFF	Kernel has downloaded Code1 to Flash 0	Yes
1	0	1	0xFFFFFFFF	0xFFFFFFFF	Code1 normal execution in Flash 0	No
2	0	1	0xFFFFFFFF	2	Code1 has downloaded Code2 to Flash 1	Yes
2	0	1	0xFFFFFFFF	2	Code1 starts a trial run on Code2 in Flash 1	No
2	0	1	0	2	Code2 trial run complete	Yes
2	0	1	0	2	Code 2 normal execution in Flash 1	No
3	0xFFFFFFFF	3	0	2	Code2 has downloaded Code3 to Flash 0	Yes
3	0xFFFFFFFF	3	0	2	Code2 starts trial run on Code3 in Flash 0	No
3	0	3	0	2	Code3 trial mode complete	Yes
3	0	3	0	2	Code3 normal execution in Flash 0	No
4	0	3	0xFFFFFFFF	4	Code3 has downloaded Code4 to Flash 1	Yes
4	0	3	0xFFFFFFFF	4	Code3 starts a trial run on Code4 in Flash 1	No
4	0	3	0	4	Code 4 trial mode complete	Yes
4	0	3	0	4	Code4 normal execution in Flash 1	No
...		
Max		9999		10000	Code1000 normal mode in Flash 1	No

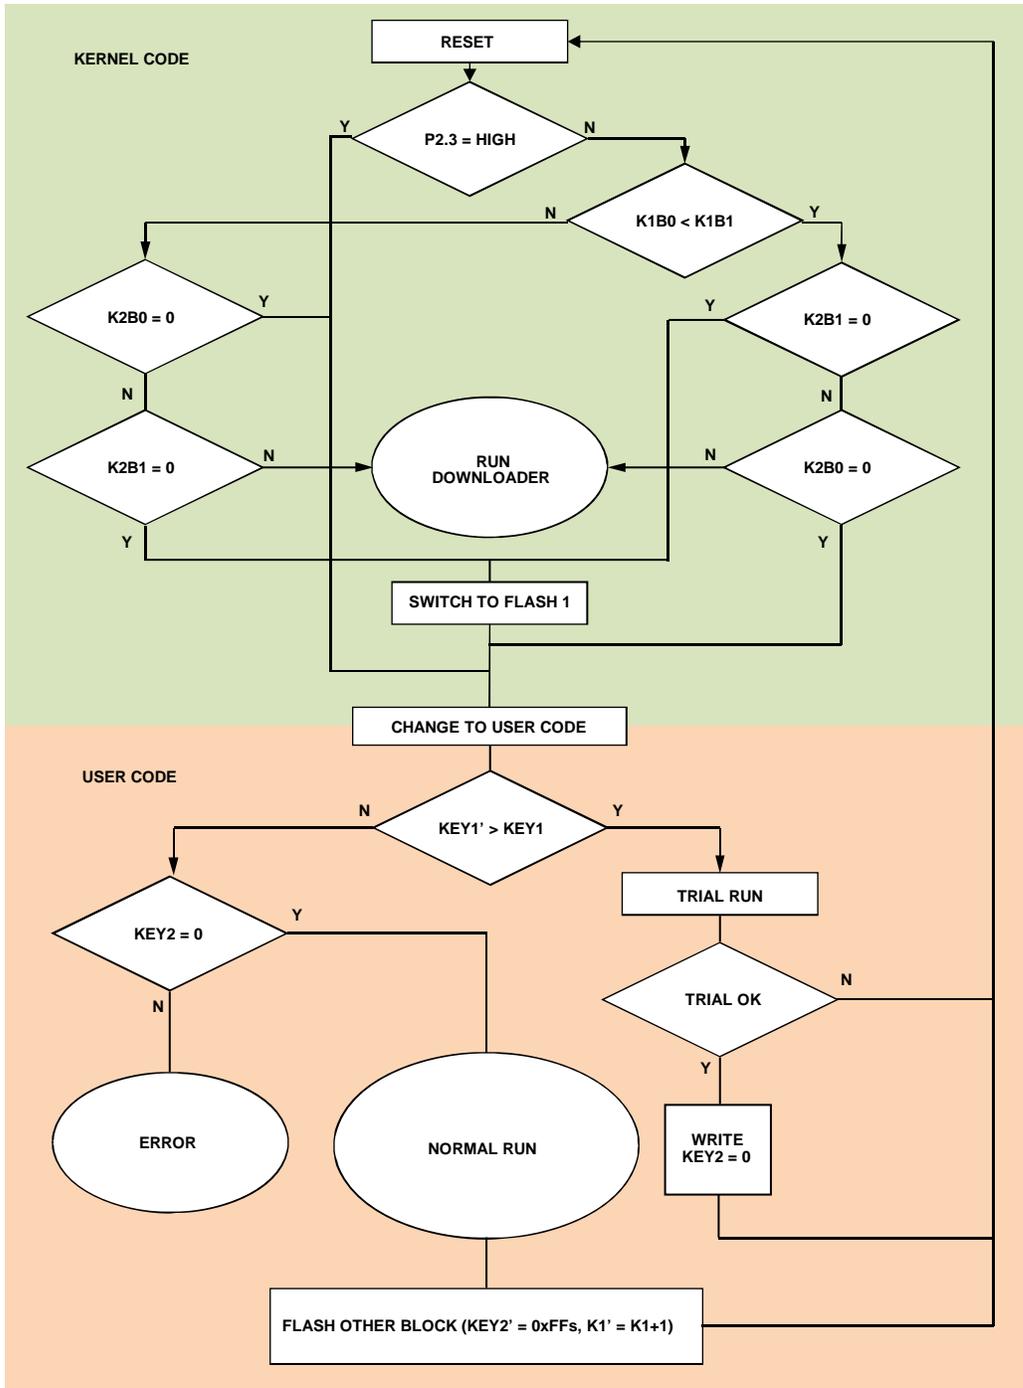

Figure 37. Flowchart for MDIO Memory Block Switching

11176-137

Table 303. Definition of Keys

Key ^{1,2}	Description
K1B0	Key1 in Flash Block 0 at 0x1DFE0.
K1B1	Key1 in Flash Block 1 at 0x3DFE0.
K2B0	Key2 in Flash Block 0 at 0x1DFE8.
K2B1	Key2 in Flash Block 1 at 0x3DFE8.
Key1	Key used to identify latest revision in active flash block at 0x1DFE0.
Key2	Key used for trial runs in active flash block at 0x1DFE8.
Key1'	Key1 for the other flash block at 0x3DFE0.
Key2'	Key2 for the other flash block at 0x3DFE8.
0xFFs	0xFFFFFFFFFFFFFFFF

¹ Key1, Key2, Key1', and Key2' refer to the keys as seen by the user.

² K1B0, K1B1, K2B0, and K2B1 refer to the keys as seen by the kernel before block switching occurs.

REGISTER SUMMARY: MDIO INTERFACE (MDIO)

Names and short descriptions of bits refer to the active state represented by a high (1) level unless explicitly enumerated.

Table 304. MDIO Register Summary

Address	Name	Description	Reset	RW
0x40005C00	MDCON	MDIO block control	0x0000	RW
0x40005C04	MDFRM	MDIO received frame control information	0x0000	R

Bits	Bit Name	Description	Reset	Access
[15:0]	MD_ADR	Received address.	0xx	R

MDIO Data for Transmission Register

Address: 0x40005C10, Reset: 0x0000, Name: MDTXD

Data to be transmitted by next Data frame.

Table 309. Bit Descriptions for MDTXD

Bits	Bit Name	Description	Reset	Access
[15:0]	MD_TXD	Data that will be transmitted by the next read or PostReadIncAdd frame.	0x0000	RW

MDIO PHYADDR Software Values and Selection and DEVADD Register

Address: 0x40005C14, Reset: 0x0400, Name: MDPHY

Sets expected values for control part of frame.

Table 310. Bit Descriptions for MDPHY

Bits	Bit Name	Description	Reset	Access
15	RESERVED	Reserved.	0x0	R
[14:10]	MD_DEVADD	Expected DEVADD. Normally 01.	0x1	RW
[9:5]	MD_PHYSEL	Selects expected PHYADR bits. For each of the 5 bits: 0: Sets expected PHYADR.x = PRTADR _x pin. 1: Sets expected PHYADR.x = MD_PHYSW.x.	0x0	RW
[4:0]	MD_PHYSW	Software provided PHYADR bits. Chosen according to corresponding MD_PHYSEL bits.	0x0	RW

MDIO Progress Signaling Through Frame Register

Address: 0x40005C18, Reset: 0x0000, Name: MDSTA

Indicates progress through frame.

Table 311. Bit Descriptions for MDSTA

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED	Reserved.	0x0	R
7	MD_PHYN	Set at end of PHYADR if PHYADR non matching . Cleared by reading MDSTA.	0x0	RC
6	MD_PHYM	Set at end of PHYADR if PHYADR matching. Cleared by reading MDSTA.	0x0	RC

Bits	Bit Name	Description	Reset	Access
5	MD_DEVN	Set at end of DEVADD if DEVADD non-matching. Cleared by reading MDSTA.	0x0	RC
4	MD_DEVM	Set at end of DEVADD if DEVADD matching. Cleared by reading MDSTA.	0x0	RC
3	MD_RDF	Set at end of Read frame. Cleared by reading MDSTA.	0x0	RC
2	MD_INCF	Set at end of PosrReadIncAdd Frame frame. Cleared by reading MDSTA.	0x0	RC
1	MD_ADRF	Set at end of Address frame. Cleared by reading MDSTA.	0x0	RC
0	MD_WRF	Set at end of Write frame. Cleared by reading MDSTA.	0x0	RC

MDIO Interrupt Enables Register

Address: 0x40005C1C, Reset: 0x0000, Name: MDIEN

Enables interrupts on specified events.

Table 312. Bit Descriptions for MDIEN

Bits	Bit Name	Description	Reset	Access
[15:8]	RESERVED	Reserved.	0x0	R
7	MD_PHYNI	If set interrupt will be requested when MD_PHYN becomes active.	0x0	RW
6	MD_PHYMI	If set interrupt will be requested when MD_PHYM becomes active.	0x0	RW
5	MD_DEVNI	If set interrupt will be requested when MD_DEVN becomes active.	0x0	RW
4	MD_DEVMI	If set interrupt will be requested when MD_DEVM becomes active.	0x0	RW
3	MD_RDFI	If set interrupt will be requested when MD_RDF becomes active.	0x0	RW
2	MD_INCFI	If set interrupt will be requested when MD_INCF becomes active.	0x0	RW
1	MD_ADRI	If set interrupt will be requested when MD_ADRF becomes active.	0x0	RW
0	MD_WRFI	If set interrupt will be requested when MD_WRF becomes active.	0x0	RW

MDIO Read PHYADDR Pins Register

Address: 0x40005C20, Reset: 0x0000, Name: MDPIN

Reads the MDIO address pins.

Table 313. Bit Descriptions for MDPIN

Bits	Bit Name	Description	Reset	Access
[15:5]	RESERVED	Reserved.	0x0	R
[4:0]	MD_PIN	Reads PRTADR pins.	0x0	R

HARDWARE DESIGN CONSIDERATIONS

TYPICAL SYSTEM CONFIGURATION

Figure 38 shows a typical [ADuCM320](#) configuration. The figure illustrates some of the hardware considerations. The four 0.47 μF capacitors on DVDD_REG1, DVDD_REG2, AVDD_REG1, and AVDD_REG2 should be placed as close as possible to the pins. VDD1 should either have a separate power supply or should be filtered from the other digital supply using an inductor bead and a resistor. The same applies to the AV_{DD} supply.

Decoupling capacitors are required between each power and associated ground as indicated in the [ADuCM320](#) data sheet. These capacitors must be placed as close as possible to the pins and in such a way that the current paths do not interfere with one another. All GNDs need to be connected together in as close to a star connection as the layout allows.

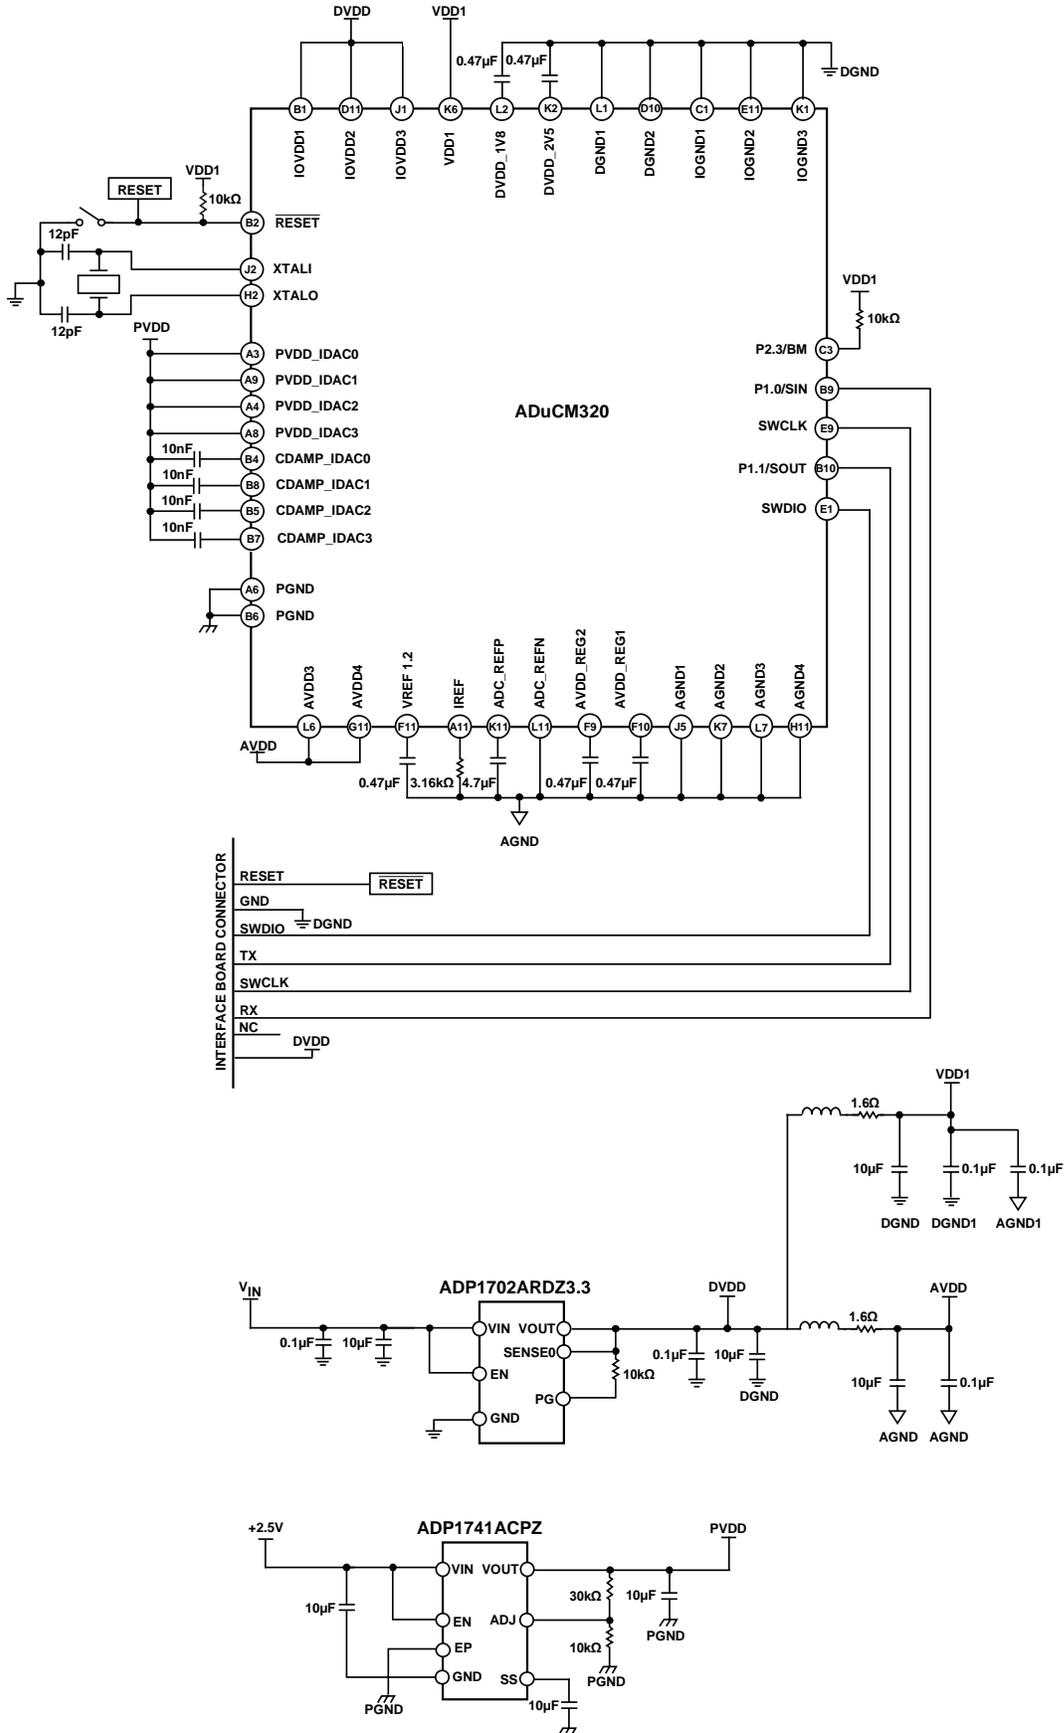

Figure 38. Typical System Configuration
Rev. 0 | Page 194 of 195

SERIAL WIRE DEBUG INTERFACE

Serial wire debug (SWD) provides a debug port for pin limited packages. SWD replaces the 5-pin JTAG port with a clock (SWDCLK) and a single bidirectional data pin (SWDIO), providing all the normal JTAG debug and test functionality. SWDIO and SWCLK are overlaid on the TMS and TCK pins on the ARM 20-pin JTAG interface.

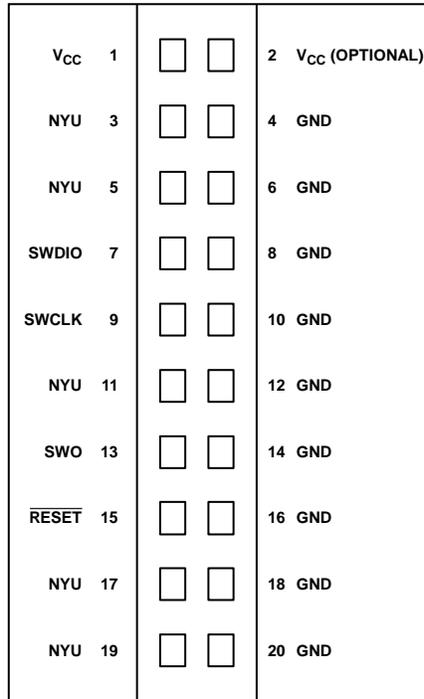

Figure 39. SWD 20-Pin Connector Pinout

Table 314. SWD Connections

Signal	Connect To
SWDIO	Data I/O pin. Use a 100 k Ω pull-up resistor to VCC.
SWO	No connect.
SWCLK	Clock pin. Use a 100 k Ω pull-up resistor to VCC.
VCC	Positive supply voltage—power supply for JTAG interface drivers.
GND	Digital ground.
RESET	No connect.

I²C refers to a communications protocol originally developed by Philips Semiconductors (now NXP semiconductors).
